Many of the designations used by manufacturers and sellers to distinguish their products are claimed as trademarks. Where those designations appear in this manual, and the author was aware of a trademark claim, the designations have been printed in initial caps or all caps.

**Contact:** In case you find bugs, errors in this manual, have proposals, or questions regarding Agena, please contact the author at: [agena.info@t-online.de](mailto:agena.info@t-online.de)

The latest release of Agena may be found at <http://agena.sourceforge.net>.

## Credits

### Chapter 7: Standard Library documentation

Large portions of Chapter 7 have been taken from the Lua 5.1 Reference Manual written by Roberto Ierusalimsky, Luiz Henrique de Figueiredo, Waldemar Celes. Used by kind permission.

#### **case of** statement

The original code was written by Andreas Falkenhahn and posted to the Lua mailing list on 01 Sep 2004. In Agenda, the functionality has been extended to check multiple values in the **of** branches.

#### **skip** statement

The **skip** functionality for loops has been written by Wolfgang Oertl and posted to the Lua Mailing List on 12 September 2005.

#### **globals** base library function

The original Lua and C code for **globals** has been written by David Manura for Lua 5.1 in 2008 and published on [www.lua.org](http://www.lua.org). Because of crashes with library C functions passed to **globals**, the C source has been patched so that in Agenda, C functions are no longer checked.

#### **md**, **cd**, and **rd** functions in the **os** library

These functions are based on code taken from the ``lposix.c`` file of the POSIX library written by Luiz Henrique de Figueiredo for Lua 5.0. These functions are themselves based on the original ones written by Claudio Terra for Lua 3.x.

#### No automatic auto-conversion of strings to numbers

was inspired by Thomas Reuben's `no_auto_conversion.patch` available at [lua.org](http://lua.org).

#### Kilobyte/Megabyte Number Suffix ('k', 'm')

taken from Eric Tetz's `k-m-number-suffix.patch` available at [lua.org](http://lua.org).

## Integer division

taken from Thierry Grellier's `newluaoperators.patch` available at [lua.org](http://lua.org).

## **bits** package

Taken from a lua-users posting by Roberto Ierusalimsky for Lua 4.0.

## Chapter One

# Introduction

# 1 Introduction

## 1.1 Features

Agena is an easy-to-learn procedural programming language suited for everyday usage. It has been implemented as an interpreter and can be used in scientific, educational, linguistic, and many other applications.

It combines features of Lua 5, Algol 60, Algol 68, Maple, ABC, SQL, ANSI C, and Sinclair ZX Spectrum BASIC.

While Agena's syntax looks like Algol 68, its implementation is based on the original Lua 5.1 sources created by Roberto Ierusalimsky, Luiz Henrique de Figueiredo, and Waldemar Celes.

Agena supports all of the common functionality found in imperative languages:

- assignments,
- loops,
- conditions,
- procedures.

Besides providing these basic operations, it has extended programming features described later in this manual, such as

- high-speed processing of complex data structures,
- fast string and mathematical operators,
- extended conditionals,
- abridged and extended syntax for loops,
- special variable increment, decrement and deletion statements,
- efficient recursion techniques,
- easy-to-use package initialisation functions,
- and much more.

Like Lua, Agena is untyped and includes the following basic data structures: numbers, strings, booleans, tables, and procedures. In addition to these types, it also supports Cantor sets, sequences, pairs, and complex values known from mathematics. With all of these types, you can easily build fast applications.

## 1.2 Features in Detail

Agena offers various flow control facilities such as

- **if/elif/else** conditions,
- **case of/else** conditions similar to C's switch/case statements,
- **is** operator to return alternative values,
- numerical **for/from/to/by** loops with optional start, stop, and step values,
- combined numerical **for/while** loops,
- **for/in** loops over strings and complex data structures,

- **while** and **do/as** loops similar to Modula's while and repeat/until not() iterators,
- a **skip** statement to prematurely trigger the next iteration of a loop,
- a **break** statement to prematurely leave a loop,
- fast and easy data type validation with the **try/else** statement and the optional double colon facility in parameter lists.

Data types provided are:

- rational and complex numbers with extensions such as **infinity** and **undefined**,
- strings,
- booleans such as **true**, **false**, and **fail**,
- the **null** value meaning 'nothing',
- multipurpose tables implemented as associative arrays to hold any kind of data, taken from Lua,
- Cantor sets as collections of unique items,
- sequences, i.e. vectors, to internally store items in strict sequential order,
- pairs to hold two values or pass arguments in any order to procedures,
- threads, userdata, and lightuserdata inherited from Lua.

For performance, most basic operations on these types were built into the Agena kernel.

Procedures with full lexical scoping are supported, as well, and provide the following extensions:

- the **<< (args) -> expression >>** syntax to easily define simple functions,
- user-defined types for procedures to allow individual handling (the same feature is available to the above mentioned tables, sets, sequences, and pairs),
- remember tables for conducting recursion at high speed and at low memory consumption,
- the **nargs** system variable which holds the number of arguments actually passed to a procedure,
- metamethods to define operations for tables, sets, sequences, and pairs, inherited from Lua.

Some other features are:

- functions to support fast text processing (see **in**, **replace**, **lower**, and **upper** operators, as well as the functions in the **strings** and **utils** packages),
- easy configuration of your personal environment via the Agena initialisation file,
- an easy-to-use package system also providing a means to load a library and define short names for all package procedures at a stroke (**with** function),
- the **binio** package to easily write and read files in binary mode,
- facility to store any data to a file and read it back later (**save** and **read** functions),
- undergraduate Calculus, Linear Algebra, and Statistics packages,
- enumeration and multiple assignment,
- the **external** switch to a numeric for loop to pass the last iteration value to its surrounding block,

- scope control via the **scope/epocs** keywords.

Agena is shipped with the packages mentioned above and all Lua C packages that are part of Lua 5.1. Some of the very basic Lua library functions have been transformed to Agena operators to speed up execution of programs and thus have been removed from the Lua packages. The Lua mathematical and string handling packages have been tuned and extended with new functions.

Agena code is not compatible to Lua. Its C API, however, was left almost unchanged and many new API functions have been added. As such, you can integrate any C package you have already written for Lua without modifying its code in 99.9 % of all cases.

### 1.3 History

I have been dreaming of creating my own programming language for the last 25 years, my first rather unsuccessful attempt made on a Sinclair ZX Spectrum in the early 1980s.

Plans became more serious in 2005 when I learned Lua to write procedures for phonetic analysis and also learned ANSI C to transfer them into a C package. In autumn 2006 the first modifications of the Lua parser began with extensive modifications and extensions of the lexer, parser and the Lua Virtual Machine in summer 2007. Most of Agena's functionality had been completed in March 2008, followed by the first new data structure, Cantor sets, one month later, some more data structures, and a lot of fine-tuning and testing thereafter. Finally, in January 2009, the first release of Agena was published at Sourceforge.

Study of many books and websites on various programming languages such as Algol 60, Algol 68, and ABC along with Maple and my various ideas on the 'perfect' language helped to conceive a completely new Algol 68-syntax based language with high-speed functionality for arithmetic and text processing.

You may find that at least the goal of designing a perfect language has not yet been met. For example, the syntax is not always consistent: you will find Algol 68-style elements in most cases, but also ABC/SQL-like syntax for basic operations with structures. The primary reason for this is that sometimes natural language statements are better to reminisce. I have stopped bothering on this inconsistency issue.

Agena has been designed on Windows 2000 and NT 4.0 using the MinGW GCC compiler. Further programming has been done on a Sun Sparc Ultra 5 and a Sun Blade 150 running Solaris 10 and on openSuSE Linux 10.3 to make the interpreter work in UNIX environments.

## Chapter Two

# Installing & Running Agenda

## 2 Installing and Running Agena

### 2.1 Solaris

In Solaris, put the gzipped Agena package into any directory. Assuming you want to install the Sparc version, uncompress the package by entering:

```
> gzip -d agena-0.22.2-sol10-sparc-local.gz
```

Then install it with the Solaris package manager:

```
> pkgadd -d agena-0.22.2-sol10-sparc-local
```

This installs the executable into the `/usr/local/bin` folder and the rest of all files into `/usr/adena`. The `/usr/adena` directory is called the `main Agena folder`.

Make sure you have the *ncurses* and *readline* libraries installed. From the command line type `adena` and press RETURN.

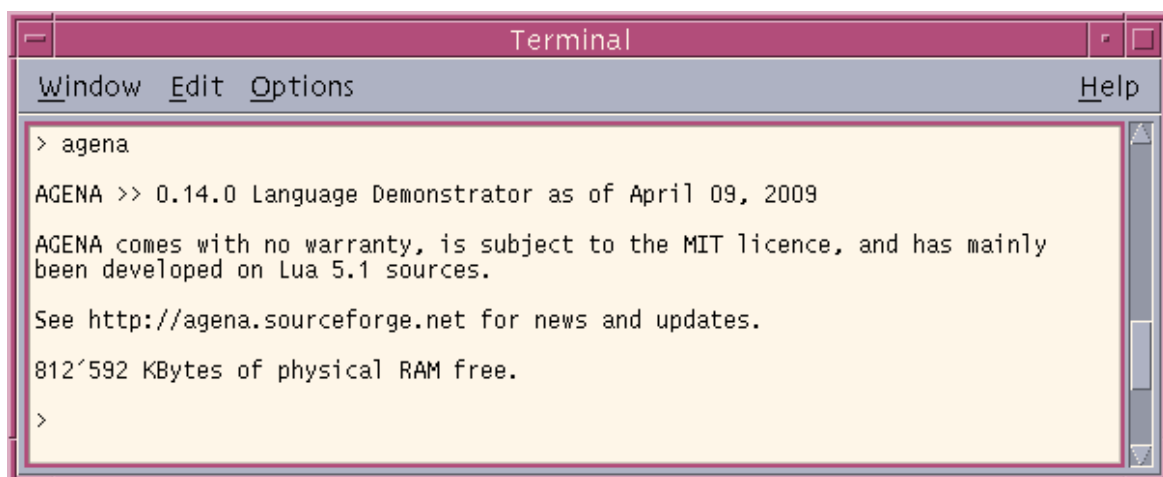

Image 1: Startup message in Solaris

The procedure for Solaris for x86 CPUs is the same. In Solaris, the package always installs as **SMCagena**.

### 2.2 Linux

In Linux, put the Agena rpm package into any directory and install it by typing:

```
> rpm -ihv agena-0.22.2-linux-i386.rpm
```

This installs the executable into the `/usr/local/bin` folder and the rest of all files into `/usr/adena`. The `/usr/adena` directory is called the `main Agena folder`. Note that you must have the *ncurses* and *readline* libraries installed before.

From the command line, type `adena` and press RETURN.

## 2.3 Windows

Just execute the Windows installer, and choose the components you want to install.

Make sure you either let the installer automatically set the environment variable called `AGENAPATH` containing the path to the main Agena folder (the default) or set it later manually in the Windows Control Panel, via the `System` icon.

You may start Agena either via the Explorer menu, or by typing `agena` in a shell.

## 2.4 OS/2 Warp 4 and eComStation

In OS/2, create a folder called `agena` anywhere on your drive, change into this directory and decompress the `agena-0.22.2-os2.zip` file. Be careful to preserve its subdirectory structure.

Now set the environment variable `AGENAPATH` in the `config.sys` file with a text editor. For example, if you installed Agena into the folder `c:\agena`, enter the following line into the `config.sys` file:

```
set AGENAPATH=c:/agena
```

Note the forward slash in the path and the environment variable name in capital letters.

Also in `config.sys`, append the path to the `agena` folder to the `PATH` system variable, so that the entry looks something like this:

```
PATH=C:\OS2;C:\OS2\MDOS;C:\;< other paths ... >;c:\agena;
```

Just enter `agena` in an OS/2 shell to run the interpreter.

## 2.5 Agena Initialisation

When you start Agena, the following actions are taken:

1. The package tables for the C libraries shipped with the standard edition of Agena (e.g. `math`, `strings`, etc.) are created so that these package procedures become available to the user.
2. All global values are copied from the `_G` table to its copy `_origG`, so that the **restart** function can restore the original environment if invoked.
3. The system variable `_EnvAgenaPath` pointing to the main Agena folder is set by either querying the environment variable `AGENAPATH` or - if not set - checking whether the current working directory contains the string `/agena`, building the path accordingly. In UNIX, if the path could not be determined as described before, `_EnvAgenaPath` is by default set to `/usr/agena`, but in Windows there is

no such fallback. The variable is used extensively in the **with** and **readlib** functions. If it could not be set, these two functions will not work, but all others will.

4. The standard Agena library `library.agn` in the `/agena/lib` folder is loaded and run. The `library.agn` file includes functions written in the Agena language that complement the C libraries. If the standard Agena library does not exist, this step is skipped without any errors.
5. An initialisation file - if present - called `agena.ini` residing in the `/agena/lib` folder is loaded and run. As with `library.agn`, this file contains code written in the Agena language that you may customise with pre-set variables, auxiliary procedures, etc. that shall be available in every Agena session. If the initialisation file does not exist, no error is issued, and the Agena session begins.

## Chapter Three

# Overview

## 3 Overview

Let us start by just entering some commands that will be described later in this manual so that you can become acquainted with Agenda as fast as possible. In this chapter, you will also learn about some of the basic data types available.

### 3.1 Input Conventions

Any valid Agenda code can be entered at the console with or without a trailing colon or semicolon:

- If an expression is finished with a colon, it is evaluated and its value is printed at the console.
- If the expression ends with a semicolon or neither with a colon nor a semicolon, it is evaluated, but nothing is printed.

You may optionally insert one or more white spaces between operands in your statements.

### 3.2 Getting familiar

Assume you would like to add the numbers 1 and 2 and show the result. Then type:

```
> 1+2:
3
```

If you want to store a value to a variable, type:

```
> c := 25;
```

Now the value 25 is stored to the name `c`, and you can refer to this number by the name `c` in subsequent calculations.

Assume that `c` is 25° Celsius. If you want to convert it to Fahrenheit, enter:

```
> 1.8*c + 32:
77
```

If you would like to compute the sum of 1 to 10, and assign the result to a variable called `r`, input:

```
> r := 0;

> for i from 1 to 10 do
>   r := r + i
> od;

> r:
55
```

There are many functions available in various libraries. To compute the arc sine, use the **arcsin** function in the **math** package;

```
> math.arcsin(1):
1.5707963267949
```

You can easily write your own functions, for example one called `deg` that converts radians to degrees.

```
> deg := << (x) -> x * 180 / Pi >>;
```

To compute the value of the function at  $\pi/4$ , just input:

```
> deg(Pi/4):
45
```

Try one of the built-in standard operators. **lower** converts all letters from upper case to lower case.

```
> lower('AGENA'):
agena
```

One of the types to hold structured values is the table, which can hold any kind of data. Assume you would like to store the birthdays of your friends, enter:

```
> birthdays := ['Neo' ~ '1970/01/01', 'Trinity' ~ '1970/12/24'];
```

Determine Neo's birthday:

```
> birthdays['Neo']:
1970/01/01
```

You can add new entries into your table.

```
> birthdays['Morpheus'] := '1952/04/01'
```

Now print its current content:

```
> birthdays:
Morpheus ~ 1952/04/01
Trinity ~ 1970/12/24
Neo ~ 1970/01/01
```

To delete entries, just type:

```
> birthdays['Morpheus'] := null

> birthdays:
Trinity ~ 1970/12/24
Neo ~ 1970/01/01
```

The global variable **ans** always holds the result of the last statement you completed with a colon.

```
> ans:
Trinity ~ 1970/12/24
Neo ~ 1970/01/01
```

The console screen can be cleared in both the Win32 and UNIX versions by just entering the keyword **cls**:

```
> cls
```

The **restart** statement resets Agena to its initial state, i.e. clears all variables you defined in a session.

```
> restart;
```

If you prefer another Agena prompt instead of the predefined one, assign:

```
> _PROMPT := 'Agena$ '
Agena$ _
```

You may put this statement into the `agena.ini` file in the Agena `lib` folder, if you do not want to change the prompt manually every time you start Agena.

### 3.3 Comments

You should always document the code you have written so that you and others will understand its meaning if reviewed later.

A single line comment starts with a single hash. Agena ignores all characters following the hash up to the end of the current line.

```
> # this is a single-line comment

> a := 1; # a contains a number
```

A multi-line comment, also called the ``long comment`` is started with the token sequence `#!/` and ends with the closing `/#` token<sup>1</sup>.

```
> /*! this is a long comment,
>    split over two lines */
```

Now let us learn more about Agena.

---

<sup>1</sup> Multi-line comments cannot begin in the very first line of a program file. Use a single comment instead.

## Chapter Four

# Data & Operations

## 4 Data & Operations

Agena features a set of data types and operations on them that are suited for both general and specialised needs. While providing all the general types inherited from Lua - numbers, strings, booleans, nulls, tables, and procedures - it also has four additional data types that allow very fast operations: sets, sequences, pairs, and complex numbers.

Type	Description
number	any integral or rational number, plus <b>undefined</b> and <b>infinity</b>
string	any text
boolean	booleans (e.g. <b>true</b> , <b>false</b> , and <b>fail</b> )
null	a value representing `nothing`
table	a multipurpose structure storing numbers, strings, booleans, tables, and any other data type
procedure	a predefined collection of one or more Agena statements
set	the classical Cantor set storing numbers, strings, booleans, and all other data types available
sequence	a vector storing numbers, strings, booleans, and all other data types except <b>null</b> in sequential order
pair	a pair of two values of any type
complex	a complex number consisting of a real and an imaginary number

Table 1: Types

Tables, sets, sequences, and pairs are also called *structures* in this manual.

### 4.1 Names, Keywords, and Tokens

In Chapter 3, we have already assigned data - such as numbers and procedures - to names, also called `variables`. These names refer to the respective values and can be used conveniently as a reference to the actual data.

A name always begins with an upper-case or lower-case letter or an underscore, followed by one or more upper-case or lower-case letters, underscores or numbers in any order.

Since Agena is a dynamically typed language, so no declarations of variable names are needed.

Valid names	Invalid names
var	lvar
_var	1_
var1	
_var1n	
_1	
ValueOne	
valueTwo	

Table 2: Examples for valid and invalid names

The following keywords are reserved and cannot be used as names:

```
abs and arctan as assigned break by bye case char clear cls copy cos
cosh dec delete dict do elif else end entier enum esac even exp external
fail false fi filled finite for from gammaln global if imag in
inc insert int intersect into is isfloat isnull join keys left ln local
lower minus nargs not null od of or proc qsadd real replace restart
return right sadd seq shift si sign sin sinh size skip split sqrt subset
tan tanh then to trim true try type typeof union unique upper while
xsubset

boolean complex lightuserdata number pair procedure sequence set
string table thread userdata
```

The following symbols denote other tokens:

```
+ - * ** / \ % ^ $ # = <> <= >= < > = == ( ) { } [ ] ; : :: @ , . .. ? `
```

## 4.2 Assignment

Values can be assigned to names in the following fashions:

```
name := value
name1, name2, ..., namek := value1, value2, ..., valuek
name1, name2, ..., namek -> value
```

In the first form, one value is stored in one variable, whereas in the second form, called 'multiple assignment statement', *name*<sub>1</sub> is set to *value*<sub>1</sub>, *name*<sub>2</sub> is assigned *value*<sub>2</sub>, etc. In the third form, called the 'short-cut multiple assignment statement', a single value is set to each name to the left of the -> operator.

First steps:

```
> a := 1;
```

```
> a:
1
```

An assignment statement can be finished with a colon to both conduct the assignment and print the right-hand side value.

```
> a := 1:
1
```

```
> a := exp(a):
2.718281828459
```

Multiple assignments:

```
> a, b := 1, 2
```

```
> a:
1
```

```
> b:
2
```

If the left-hand side contains more names than the number of values on the right-hand side, then the excess names are set to **null**.

```
> c, d := 1
```

```
> c:
1
```

```
> d:
null
```

A short-cut multiple assignment statement:

```
> x, y -> exp(1);
```

```
> x:
2.718281828459
```

```
> y:
2.718281828459
```

### 4.3 Enumeration

Enumeration with step size 1 is supported with the **enum** statement:

```
enum name1 [, name2, ... ]
enum name1 [, name2, ... ] from value
```

In the first form, *name*<sub>1</sub>, *name*<sub>2</sub>, etc. are enumerated starting with the numeric value 1.

```
> enum ONE, TWO;
```

```
> ONE:
1
```

```
> TWO:
2
```

In the second form, enumeration starts with the numeric value passed right after the **from** keyword.

```
> enum THREE, FOUR from 3
```

```
> THREE:
3

> FOUR:
4
```

## 4.4 Deletion

You may delete the contents of one or more variables with one of the following methods: Either use the **clear** command:

**clear** *name<sub>1</sub>* [, *name<sub>2</sub>*, ..., *name<sub>k</sub>*]

```
> a := 1;

> clear a;

> a:
null
```

which also performs a garbage collection useful if large structures shall be removed from memory, or set the variable to be deleted to **null**:

```
> b := 1;

> b := null:
null
```

The **null** value represents the absence of a value. All names that are unassigned evaluate to **null**. Assigning names to **null** quickly clears their values, but does not garbage collect them.

## 4.5 Precedence

Operator precedence in Agena follows the table below, from lower to higher priority:

```
or
and
< > <= >= = <>
in subset xsubset union minus intersect
.. :
+ - split
* / % \ shift
not -(unary) !
^ **
```

As usual, you can use parentheses to change the precedence of an expression. The concatenation (..), exponentiation (^, \*\*) and pair (:) operators are right associative, e.g.  $x^y^z = x^{(y^z)}$ . All other binary operators are left associative.

```
> 1+3*4:
13
```

```
> (1+3)*4:
16
```

## 4.6 Arithmetic

### 4.6.1 Numbers

In the `real` domain, Agenda internally only knows floating point numbers which can represent integral or rational numeric values. All numbers are of type number.

An integral value consists of one or more numbers, with an optional sign in front of it.

- 1
- -20
- 0
- +4

A rational value consists of one or more numbers, an obligatory decimal point at any position and an optional sign in front of it:

- -1.12
- 0.1
- .1

Negative integral or rational values must always be entered with a minus sign, but positive numbers do not need to have a plus sign.

You may optionally include one or more single quotes *within* a number to group digits:

```
> 10'000'000:
10000000
```

You can alternatively enter numbers in scientific notation using the `e` symbol.

```
> 1e10:
10000000000
```

```
> -1e-4:
-0.0001
```

If a number ends with the letter `K`, `M`, `G`, or `D`, then the number is multiplied with 1,024, 1,048,576 (= 1,024<sup>2</sup>), 1,073,741,824 (= 1,024<sup>3</sup>), or 12, respectively. If a number ends with the letter `k` or `m`, then the number is multiplied with 1,000 or 1,000,000, respectively.

```
> 2k:
2000
```

```
> 1M:
1048576

> 12D:
144
```

If you use only real numbers in your programs, then Agena will calculate only in the real domain. If you use at least one complex value (see Chapter 4.6.5), then Agena will calculate in the complex domain.

### 4.6.2 Arithmetic Operations

Agena has the following arithmetical operators:

Operator	Operation	Details / Example
+	Addition	$1 + 2 \gg 3$
-	Subtraction	$3 - 2 \gg 1$
*	Multiplication	$2 * 3 \gg 6$
/	Division	$4 / 2 \gg 2$
^	Exponentiation with rational power	$2 ^ 3 \gg 8$
**	Exponentiation with integer power	faster than $^$ , $2 ** 3 \gg 8$
%	Modulus	$5 \% 2 \gg 1$
\	Integer division	$5 \setminus 2 \gg 2$
shift	Bitwise shift	If the right-hand side is positive, the bits are shifted to the left (multiplication with 2), else they are shifted to the right (division by 2).

Table 3: Arithmetic operators

Agena has a lot of mathematical functions both built into the kernel and also available in the **math**, **stats**, **linalg**, and **calc** libraries. Table 4 shows some of the most common.

The mathematical procedures that reside in packages must always be entered by passing the name of the package followed by a dot and the name of the procedure<sup>2</sup>.

Unary operators<sup>3</sup> like **ln**, **exp**, etc. can be entered with or without simple brackets.

Procedure	Operation	Library	Example and result
<b>sin</b> (x)	Sine (x in radians)	Kernel	<code>sin(0) &gt;&gt; 0</code>
<b>cos</b> (x)	Cosine (x in radians)	Kernel	<code>cos(0) &gt;&gt; 1</code>
<b>tan</b> (x)	Tangent (x in radians)	Kernel	<code>tan(1) &gt;&gt; 1.557407..</code>
<b>arcsin</b> (x)	Arc sine (x in radians)	math	<code>math.arcsin(0) &gt;&gt; 0</code>

<sup>2</sup> Check the **with** function which provides an easy way to define short names for package procedures.

<sup>3</sup> See Appendix A1 for a list of all unary operators.

Procedure	Operation	Library	Example and result
<b>arccos</b> (x)	Arc cosine (x in radians)	math	math.arccos(0) » 1.570796....
<b>arctan</b> (x)	Arc tangent (x in radians)	Kernel	arctan(Pi) » 1.262627..
<b>sinh</b> (x)	Hyperbolic sine	Kernel	sinh(0) » 0
<b>cosh</b> (x)	Hyperbolic cosine	Kernel	cosh(0) » 1
<b>tanh</b> (x)	Hyperbolic tangent	Kernel	tanh(0) » 0
<b>abs</b> (x)	Absolute value of x	Kernel	abs(-1) » 1
<b>entier</b> (x)	Rounds x downwards to the nearest integer	Kernel	entier(2.9) » 2 entier(-2.9) » -3
<b>even</b> (x)	Checks whether x is even	Kernel	even(2) » true
<b>exp</b> (x)	Exponentiation $e^x$	Kernel	exp(0) » 1
<b>gammaln</b> (x)	$\ln \Gamma x$	Kernel	exp(gammaln(3+1)) » 6
<b>int</b> (x)	Rounds x to the nearest integer towards zero	Kernel	int(2.9) » 2 int(-2.9) » -2
<b>ln</b> (x)	Natural logarithm	Kernel	ln(1) » 0
<b>log</b> (x, b)	Logarithm of x to the base b	math	math.log(8, 2) » 3
<b>roundf</b> (x, d)	Rounds the real value x to the d-th digit	math	math.roundf( sqrt(2), 2) » 1.41
<b>sign</b> (x)	Sign of x	Kernel	sign(-1) » -1
<b>sqrt</b> (x)	Square root of x	Kernel	sqrt(2) » 1.414213..
<b>sadd</b> ([...])	Sum	Kernel	sadd([1, 2, 3]) » 6
<b>mean</b> ([...])	Arithmetic mean	stats	stats.mean([1, 2, 3]) » 2
<b>median</b> ([...])	Median	stats	stats.median( [1, 2, 3, 4]) » 2.5

Table 4: Common mathematical functions

### 4.6.3 Increment and Decrement

Instead of incrementing or decrementing a value, say

```
> a := 1;
```

by entering a statement like

```
> a := a + 1:
2
```

you can use the **inc** and **dec** commands<sup>4</sup> which are also around 10% faster:

```
inc name [, value]
dec name [, value]
```

If *value* is omitted, *name* is increased or decreased by 1.

<sup>4</sup> Finishing an **inc** or **dec** statement with a colon instead of a semicolon does not work.

```

> inc a;

> a:
3

> dec a;

> a:
2

> inc a, 2;

> a;
4

> dec a, 3;

> a:
1

```

#### 4.6.4 Mathematical Constants

Agena features the following arithmetic constants:

Constant	Meaning
<b>degrees</b>	Factor $1/\text{Pi} \times 180$ to convert radians to degrees
<b>EnvEps</b>	Equals $1.4901161193847656\text{e-}08$
<b>Exp</b>	Constant $e = \exp(1) = 2.71828182845904523536$
<b>I</b>	Imaginary unit
<b>infinity</b>	Infinity
<b>Pi</b>	Constant $\text{pi} = 3.14159265358979323846$
<b>radians</b>	Factor $\text{Pi}/180$ to convert degrees to radians
<b>undefined</b>	An expression stating that it is undefined, e.g. a singularity

Table 5: Arithmetic constants

#### 4.6.5 Complex Math

Complex numbers can be defined in two ways: by using the `!` constructor or the imaginary unit represented by the capital letter `I`. Most of Agena's mathematical operators and functions know how to handle complex numbers and will always return a result that is in the complex domain.

```

> a := 1!1;

> b := 2+3*I;

> a+b:
3+4*I

> a*b:
-1+5*I

```

The following operators work on rational numbers as well as complex values: `+`, `-`, `*`, `/`, `^`, `**`, `=`, `<>`, `abs`, `arctan`, `cos`, `entier`, `exp`, `ln`, `sign`, `sin`, `sqrt`, `tan`, and unary minus. With these operators, you can also mix numbers and complex numbers in

expressions. You will find that most functions of the **math** package are also applicable to complex values.

Note that the **!** operator has the same precedence as unary operators like **-**, **sin**, **cos**, etc. This means that  $-1!2 = 1-I$ , but also  $\sin 1!2 = (\sin 1)!2$ . It is advised that you use brackets when applying unary operators on complex values.

Complex values are of type **complex**.

## 4.7 Strings

Any text can be represented by including it in single or double quotes:

```
> 'This is a string':
This is a string
```

Of course, strings - like numbers - can be assigned to variables.

```
> str := "I am a string.";

> str:
I am a string.
```

Strings can be of almost unlimited length. Strings can be concatenated, characters or sequences of characters can be replaced by other ones, and there are various other functions to work on strings.

Multiline-strings can be entered in two fashions: If you use single quotes, put a backslash at the end of each line except the last one:

```
> str := 'Two\
lines';
```

When using double quotes, backslashes are not needed:

```
> str := "Two
lines";
```

A string may contain no text at all - called an empty string -, represented by two consecutive single quotes with no spaces or characters between them:

```
> '':
```

You may obtain a specific character by passing a dollar sign and its position in simple brackets right behind the string name. If you use a negative index *n*, then the *n*-th character from the right end of the string is returned.

```
> str := 'I am a string.';

> str$(1);
I
```

In general, parts of a string consisting of one or more consecutive characters can be obtained with the substring notation.

$$stringname\$( start [, end] )$$

You must at least pass the starting position of the substring. If only *start* is given then the single character at position *start* is returned. If *end* is given too, then the substring starting at position *start* up to and including position *end* is returned.

```
> str := 'string'
> str$(3):
r
> str$(3, 5):
rin
> str$(3, 3):
r
```

You may also pass negative values for *start* and/or *end*. In these cases, the positions are determined with respect to the right end of the string.

```
> str$(3, -1):
ring
> str$(3, -2):
rin
> str$(-3):
i
```

If you want to retrieve only one single character from a string, you may also use the faster indexing method:

$$stringname[pos]$$

This returns the character in *stringname* that is at position *pos*. If you pass a negative for *pos*, then the  $|pos|$ -th character from the right end of the string is returned.

```
> str := 'string'
> str[2]:
t
> str[-1]:
g
```

In Agena, a text can include any escape sequences known from ANSI C, e.g.:

- `\n`: inserts a new line,
- `\t`: inserts a tabulator
- `\b`: puts the cursor one position to the left but does not delete any characters.

```
> 'I am a string.\nMe too.':
I am a string.
Me too.
```

```
> 'These are numbers: 1\t2\t3':
These are numbers: 1      2      3
```

```
> 'Example with backspaces:\b but without the colon.':
Example with backspaces but without the colon.
```

If you want to put a single or double quote into the string, put a backslash right in front of it:

```
> 'A quote: \''':
A quote: '
```

```
> "A quote: '\"":
A quote: "
```

Likewise, a backslash is inserted by typing it twice.

Two or more strings can be concatenated with the `..` operator:

```
> 'First string, ' .. 'second string, ' .. 'third string':
First string, second string, third string
```

Instead of putting single or double quotes around a text, you may also use a back quote in front of the text, but not at its end. The string then automatically ends with one of the following tokens<sup>5</sup>:

```
<space> " , ~ [ ] { } ( ) ; : # ' = ? & % $ § \ ! ^ @ < > | \r \n \t
```

This also allows UNIX-style filenames to be entered using this short-cut method.

```
> `text:
text

> `/proglang/adena/utills/utills.agn:
/proglang/adena/utills /utills.agn
```

Agenda has basic operators useful for text processing:

---

<sup>5</sup> For the current settings of your Agenda version see bottom of the `agnconf.h` file in the `src` directory of the distribution.

Operator	Return	Function
<code>s in t</code>	number or <b>null</b>	Checks whether a substring <code>s</code> is included in string <code>t</code> . If true, the position of the first occurrence of <code>s</code> in <code>t</code> is returned; otherwise <b>null</b> is returned.
<code>replace(s, p, r)</code>	string	Replaces all patterns <code>p</code> in string <code>s</code> with substring <code>r</code> . If <code>p</code> is not in <code>s</code> , then <code>s</code> is returned unchanged.
<code>s split d</code>	table of strings	Splits a string into its words with <code>d</code> as the delimiting character. The items are returned as a sequence of strings.
<code>size(s)</code>	number	Returns the length of string <code>s</code> . If <code>s</code> is the empty string, 0 is returned.
<code>abs(s)</code>	number	Returns the numeric ASCII code of character <code>s</code> .
<code>char(n)</code>	string	Returns the character corresponding to the given numeric ASCII code <code>n</code> .
<code>lower(s)</code>	string	Converts a string to lowercase. Western European diacritics are recognised.
<code>upper(s)</code>	string	Converts a string to uppercase. Western European diacritics are recognised.
<code>trim(s)</code>	string	Deletes leading and trailing spaces as well as excess embedded spaces.

Table 6: String operators

Some examples:

```
> str := 'a string';
```

The character ``s`` is at the third position:

```
> 's' in str:
3
```

Let us split a string into its components that are separated by white spaces:

```
> str split ' ':
seq(a, string)
```

`str` is eight characters long:

```
> size(str):
8
```

The ASCII code of the first character in `str`, `a`, is:

```
> abs(str[1]):
97
```

translated back to

```
> char(ans):
a
```

Put all characters in str to uppercase:

```
> upper(str):
A STRING
```

And now the reverse:

```
> lower(ans):
a string
```

The **replace** functionality easily replaces all occurrences of a substring with another one:

```
> replace(str, 'string', 'text'):
a text
```

A string always is of type **string**.

```
> type(str):
string
```

## 4.8 Boolean Expressions

Agena supports the logical values **true** and **false**, also called `booleans`. Any condition, e.g.  $a < b$ , results to one of these logical values. They are often used to tell a program which statements to execute and thus which statements not to execute.

Boolean expressions always result to the boolean values **true** or **false**. Boolean expressions are created by:

- relational operators ( $>$ ,  $<$ ,  $=$ ,  $==$ ,  $<=$ ,  $>=$ ,  $<>$ ),
- logical operators (**and**, **or**, **not**),
- logical names: **true**, **false**, **fail**, and **null**,
- **in**, **subset**, **xsubset**, and various functions.

Agena supports the following relational operators:

Operator	Description	Example
$<$	less than	$1 < 2$
$>$	greater than	$2 > 1$
$<=$	less than or equals	$1 <= 2$
$>=$	greater than or equals	$2 >= 1$
$=$	equals	$1 = 1$
$==$	strict equals for structures	$[1] == [1]$ $1 == 1$
$<>$	not equals	$1 <> 2$

Table 7: Relational operators

Logical operators are:

Operator	Description	Examples
and	Both operands must evaluate to <b>true</b> so that the boolean expression results to <b>true</b> . Otherwise the result is <b>false</b> .	true and true » true false and false » false true and false » false false and true » false
or	At least one of the operands must evaluate to <b>true</b> so that the boolean expression results to <b>true</b> . If neither of the operands is true, the expression is <b>false</b> .	true or true » true true or false » true false or true » true false or false » false
not	Turns a true expression to <b>false</b> and vice versa.	not true » false not false » true

Table 8: Logical operators

As expected, you can assign boolean expressions to names

```
> cond := 1 < 2:
true

> cond := 1 < 2 or 1 > 2 and 1 = 1:
true
```

or use them in **if** statements.

In many situations, the **null** value can be used synonymously for **false**.

The Boolean constant **fail** can be used to denote an error. With boolean operators (**and**, **or**, **not**), **fail** behaves like the **false** constant, but remember that **fail** is always unlike **false**, i.e. **fail** = **false** results to **false**.

**true**, **false**, and **fail** are of type **boolean**. **null**, however, has its own type **null**.

## 4.9 Tables

Tables are used to represent any more complex data structure. Tables consist of zero, one or more key-value pairs: the key referencing to the position of the value in the table, and the value the data itself.

Keys and values can be numbers, strings, and any other data type except **null**.

Here is a first example: Suppose you want to create a table with the following meteorological data from Viking Lander 1 which landed on Mars in 1976:

Sol	Pressure in mb	Temperature in °C
1.02	7.71	-78.28
1.06	7.70	-81.10
1.10	7.70	-82.96

```
> VL1 := [
>   1.02 ~ [7.71, -78.28],
>   1.06 ~ [7.70, -81.10],
>   1.10 ~ [7.70, -82.96]
> ];
```

To get the data of Sol 1.02 (the Marsian day #1.2) input:

```
> VL1[1.02]:
[7.71, -78.28]
```

Tables may be empty, or include other tables - even nested ones.

You can control how tables are printed at the console in two ways: If the global environment variable `_EnvLongTable` is set to true, then each key~value pair is printed at a separate line, like in the example above. If `_EnvLongTable` is set to false, or is unassigned, key~value pairs will be printed in one line. Also, you can define your own printing function that tells the interpreter how to print a table (or other structures). In this case, the setting of `_EnvLongTable` will be ignored. See the Appendix for further information on how to do this.

Stripped down versions of tables are sets and sequences which are described later. Most operations on tables introduced in this chapter are also applicable to sets and sequences.

## 4.9.1 Arrays

Agenda features two types of tables, the simplest one being the *array*. Arrays are created by putting their values in square brackets:

$$[[value_1 [, value_2, \dots]]]$$

```
> A := [4, 5, 6]:
[4, 5, 6]
```

The numbers 1, 2, and 3 are the *keys* or *indices* of table A. The corresponding table *values* are 4, 5, and 6. With arrays, the indices always start with 1 and count upwards sequentially. The keys are always integral, so A in this example is an array whereas VL in the last chapter is not.

To refer to a table value, enter the name of the table followed by the respective index in square brackets:

$$tablename[key]$$

```
> A[1]:
4
```

If a table contains other tables, you may get their values by passing the respective keys in consecutive order:

$$tablename[key_1][key_2][\dots]$$

```
> A := [[3, 4]]:
[[3, 4]]
```

The following call refers to the complete inner table which is at index 1 of the outer table:

```
> A[1]:
[3, 4]
```

The next call returns the second element of the inner table.

```
> A[1][2]:
4
```

Tables may be nested:

```
> A := [4, [5, [6]]]:
[4, [5, [6]]]
```

To get the number 6, enter the position of the inner table [5, [6]] as the first index, the position of the inner table [6] as the second index, and the position of the desired entry as the third index:

```
> A[2][2][1]:
6
```

Tables can contain no values at all. In this case they are called *empty tables* with values to be inserted later in a session. There are two forms to create empty tables.

$$\text{create table } name_1 [, \text{table } name_2, \dots]$$

$$name_1 := [ ]$$

```
> create table B;
```

creates the empty table B,

```
> B := [ ];
```

does exactly the same.

You may add a value to a table by assigning the value to an indexed table name:

```
> B[1] := 'a';
```

```
> B:
1 ~ a
```

Alternatively, the **insert** statement always appends values to the end of a table:

**insert** *value*<sub>1</sub> [, *value*<sub>2</sub>, ...] **into** *name*

```
> insert 'b' into B;
```

```
> B:
[a, b]
```

To delete a specific key~value pair, assign **null** to the indexed table name:

```
> B[1] := null;
```

```
> B:
[2 ~ b]
```

The **delete** statement works a little bit differently and removes all occurrences of a value from a table.

**delete** *value*<sub>1</sub> [, *value*<sub>2</sub>, ...] **from** *name*

```
> insert 'b' into B;
```

```
> delete 'b' from B;
```

```
> B:
[]
```

In both cases, deletion of values leaves `holes` in a table, which are **null** values between other non-**null** values:

```
> B := [1, 2, 2, 3]
```

```
> delete 2 from B
```

```
> B:
[1 ~ 1, 4 ~ 3]
```

There exists a special sizing option with the **create table** statement which besides creating an empty table also sets the default number of entries. Thus you may gain some speed if you perform a large number of subsequent table insertions, since with each insertion, Agenda checks whether the maximum number of entries has been reached. If so, each time it automatically enlarges the table which creates some overhead. The sizing option reserves memory for the given number of elements in advance, so there is no need for Agenda to subsequently enlarge the table until the default size will be exceeded.

Arrays with a predefined number of entries are created according to the following syntax:

**create table**  $name_1(size_1)$  [, **table**  $name_2(size_2)$ , ...]

When assigning entries to the table, you will save at least 1/3 of computation time if you know the size of the table in advance and initialise the table with it. If you want to insert more values later, then this will be no problem. Agena automatically enlarges the table beyond its initial size if needed.

```
> create table a(5);
> create table a, table b(5);
```

### 4.9.2 Dictionaries

Another form of a table is the *dictionary* with any kind of data - not only positive integers - as indices:

Dictionaries are created by explicitly passing key-value pairs with the respective keys and values separated by tildes, which is the difference to arrays:

[ [ $key_1 \sim value_1$  [,  $key_2 \sim value_2$ , ...]] ]

```
> A := [1 ~ 4, 2 ~ 5, 3 ~ 6]:
[1 ~ 4, 2 ~ 5, 3 ~ 6]

> B := [abs('p') ~ 'th']:
[231 ~ th]
```

Here is another example with strings as keys:

```
> dic := ['donald' ~ 'duck', 'mickey' ~ 'mouse'];
> dic:
[mickey ~ mouse, donald ~ duck]
```

As you see in this example, Agena internally stores the key-value pairs of a dictionary in an arbitrary order.

As with arrays, indexed names are used to access the corresponding values stored to dictionaries.

```
> dic['donald']:
duck
```

If you use strings as keys, a short form is:

```
> dic.donald:
duck
```

Further entries can be added with assignments such as:

```
> dic['minney'] := 'mouse';
```

which is the equivalent to

```
> dic.minney := 'mouse';
```

Dictionaries with an initial number of entries are declared like this:

**create dict** *name<sub>1</sub>(size<sub>1</sub>)* [, **dict** *name<sub>2</sub>(size<sub>2</sub>)*, ...]

You may mix declarations for arrays and dictionaries, so the general syntax is:

**create** {**table** | **dict**} *name<sub>1</sub>[(size<sub>1</sub>)]* [, {**table** | **dict**} *name<sub>2</sub>[(size<sub>2</sub>)]*, ...]

### 4.9.3 Table, Set and Sequence Operators

Agena features some built-in table, set and sequence operators which are shown in Table 6. A `structure` in this context is a table, set, or sequence.

Operator	Return	Function
<b>c in A</b>	Boolean	Checks whether the structure A contains the given value c.
<b>filled A</b>	Boolean	Determines whether a structure contains at least one value. If so, it returns <b>true</b> , else <b>false</b> .
<b>A = B</b>	Boolean	Checks whether two tables A, B, or two sets A, B, or two sequences A, B contain the same values regardless of the number of their occurrence; if B is a reference to A, then the result is also <b>true</b> .
<b>A == B</b>	Boolean	Checks whether two tables A, B, or two sets A, B, or two sequences A, B contain the same number of elements and whether all key~value pairs in the tables or entries in the sets or sequences are the same; if B is a reference to A, then the result is also <b>true</b> .
<b>A &lt;&gt; B</b>	Boolean	Checks whether two sets/tables/sequences A, B do not contain the same values regardless of the number of their occurrence; if B is a reference to A, then the result is <b>false</b> .
<b>A subset B</b>	Boolean	Checks whether the values in structure A are also values in B regardless of the number of their occurrence. The operator also returns <b>true</b> if A = B.

Operator	Return	Function
<b>A xsubset B</b>	Boolean	Checks whether the values in structure A are also values in B. Contrary to <b>subset</b> , the operator returns <b>false</b> if $A = B$ .
<b>A union B</b>	table, set, seq	Concatenates two tables, or two sets, or two sequences A, B simply by copying all its elements - even if they occur multiple times - to a new structure. With sets, all items in the resulting set will be unique, i.e. they will not appear multiple times.
<b>A intersect B</b>	table, set, seq	Returns all values in two tables, two sets, or two sequences A, B that are included both in A and in B as a new structure.
<b>A minus B</b>	table, set, seq	Returns all the values in A that are not in B as a new structure.
<b>copy A</b>	table, set, seq	Creates a deep copy of the structure A, i.e. if A includes other tables, sets, or sequences, copies of these structures are built, too.
<b>join A</b>	string	Concatenates all strings in the table or sequence A.
<b>size A</b>	number	Returns the size of a table A, i.e. the actual number of key~value pairs in A. With sets and sequences, the number of items is returned.
<b>sort A</b>	table, seq	Sorts table or sequence A in ascending order. It directly operates on A, so it is destructive. With tables, the function has no effect on values that have non-integer keys.
<b>unique A</b>	table, seq	Removes multiple occurrences of the same value and returns the result in a new structure. With tables, also removes all holes (‘missing keys’) by reshuffling its elements. This operator is not applicable to sets, since they are already unique.
<b>sadd A</b>	number	Sums up all numeric table or sequence values. If the table or sequence is empty or contains no numeric values, <b>null</b> is returned. Sets are not supported.
<b>qsadd A</b>	number	Raises each value in a table or sequence to the power of 2 and sums up these powers. If the table or sequence is empty or contains no numeric values, <b>null</b> is returned. Sets are not supported.

Table 9: Table, set, or sequence and set operators

Here are some examples - try them with sets and sequences as well:

The **union** operator concatenates two tables simply by copying all its elements - even if they occur multiple times.

```
> ['a', 'b', 'c'] union ['a', 'd']:
[a, b, c, a, d]
```

**intersect** returns all values that are part of both tables as a new table.

```
> ['a', 'b', 'c'] intersect ['a', 'd']:
[a]
```

If a value appears multiple times in the set at the left hand side of the operator, it is written the same number of times to the resulting table.

**minus** returns all the elements that appear in the table on the left hand side of this operator that are not members in the right side table.

```
> ['a', 'b', 'c'] minus ['a', 'd']:
[b, c]
```

If a value appears multiple times in the set at the left hand side of the operator, it is written the same number of times to the resulting table.

The **unique** operator

- removes all holes ( `missing keys` ) in a table,
- removes multiple occurrences of the same value.

and returns the result in a new table. The original table is *not* overwritten. In the following example, there is a hole at index 2 and the value 'a' appears twice.

```
> unique [1 ~ 'a', 3 ~ 'a', 4 ~ 'b']
```

returns [b, a].

You can search a table for a specific value with the **in** operator. It returns **true** if the value has been found, or **false**, if the element is not part of the set. Examples:

```
> 'a' in ['a', 'b', 'c']
```

returns **true**.

```
> 1 in ['a', 'b', 'c']
```

returns **false**. Remember that **in** checks the *values* of a table, not its keys.

#### 4.9.4 Table Functions

Agena has a number of functions to work on tables only. The most basic are:

Function	Description	Further detail
<b>tables.put</b> ( <i>t</i> , <i>key</i> , <i>value</i> )	Inserts index <i>key</i> with value <i>value</i> to table <i>t</i> .	It shifts up the original element at position <i>key</i> and all other elements to the right.
<b>tables.remove</b> ( <i>t</i> , <i>key</i> )	Removes index <i>key</i> and its corresponding value from <i>t</i> .	All elements to the right are shifted down, so that no holes are created.

Table 10: Basic table procedures

#### 4.9.5 Table References

If you assign a table to a variable, only a reference to the table is stored in the variable. This means that if we have a table

```
> A := [1, 2];
```

assigning

```
> B := A;
```

does not copy the contents of A to B, but only the address of the same memory area which holds table [1, 2]; hence:

```
> insert 3 into A;
```

```
> A:
[1, 2, 3]
```

also yields:

```
> B:
[1, 2, 3]
```

Use **copy** to create a true copy of the contents of a table. If the table contains other tables, sets, sequences, or pairs, copies of these structures are also made (so-called ‘deep copies’). Thus **copy** returns a new table without any reference to the original one.

```
> B := copy(A);
```

```
> insert 4 into A;
```

```
> B:
[1, 2, 3]
```

With structures such as tables, sets, pairs, or sequences, all names to the left of an

-> operator will point to the very same structure to its right. This behaviour may be changed in a future version of Agena.

```
> A, B -> []
> A[1] := 1
> B:
1 ~ 1
```

## 4.10 Sets

Sets are collections of unique items: numbers, strings, and other data. Their syntax is:

$$\{ [ item_1 [, item_2, \dots] ] \}$$

Thus, they are equivalent to Cantor sets: An item is stored only once:

```
> A := {1, 1, 2, 2}:
{1, 2}
```

Besides being commonly used in mathematical applications, they are also useful to hold word lists where it only matters to see whether an element is part of a list or not:

```
> colours := {'red', 'green', 'blue'};
```

If you want to check whether the colour red is part of the set colours, just index it as follows:

$$setname[element]$$

If an element is stored to a set, Agena returns **true**:

```
> colours['red']:
true
```

If an item is not in the given set, the return is **false**.

```
> colours['yellow']:
false
```

If you want to add or delete items to or from a set, use the **insert** and **delete** statements. The standard assignment statement `setname[key] := value` is not supported with sets.

**insert**  $item_1$  [,  $item_2$ , ...] **into**  $name$

**delete**  $item_1$  [,  $item_2$ , ...] **from**  $name$

```
> insert 'yellow' into colours;
```

The **in** operator checks whether an item is part of a set - it is an alternative to the indexing method explained above, and returns **true** or **false**, too.

```
> 'yellow' in colours:
true
```

The data type of a set is **set**.

```
> type(colours):
set
```

You may predefine sets with a given number of entries according to the following syntax:

**create set**  $name_1$  [ ( $size_1$ ) ] [, **set**  $name_2$  [ ( $size_2$ ) ], ...]

When assigning items later, you will save at least 90 % of computation time if you know the size of the set in advance and initialise it with the maximum number of future entries as explained above. More items than stated at initialisation can be entered anytime, since Agena automatically enlarges the respective set accordingly and will also reserves space for further entries.

Sets are useful in situations where the number of occurrences of a specific item or its position does not matter. Compared to tables, sets consume around 40 % less memory, and operations with them are 10 % to 33 % faster than the corresponding table operations.

Specifically, the more items you want to store, the faster operations will be compared to tables.

Note that if you assign a set to a variable, only a reference to the set is stored in the variable. Thus in a statement like  $A := \{ \}$ ;  $B := A$ , A and B point to the same set.

As with tables, sets support metamethods which you can be defined to extend the functionality of Agena operators. Metamethods will be explained later in Chapter 6.15.

## 4.11 Sequences

Besides storing values in tables or sets, Agenda also features the sequence, an object which can hold any number of items except **null**. You may sequentially add items and delete items from it<sup>6</sup>.

Sequences store items in sequential order. Like in tables, an item may be included multiple times. Sequences are indexed with positive integers in the same fashion as table arrays are, starting at index 1.

Metamethods for operator overloading that allow to extend the functionality of the built-in Agenda operators to sequences are supported, too (see Chapter 6.15 for more details). A sequence may hold no, one or more items.

Suppose we want to define a sequence of two values. You may enter these values into the sequence using the **seq** operator.

**seq**( [ *item*<sub>1</sub> [, *item*<sub>2</sub>, ...] ] )

```
> a := seq(0, 1);
> a:
seq(0, 1)
```

You may access the items the usual way:

*seqname*[*numeric\_key*]

```
> a[1]:
0
> a[2]:
1
```

If the index is larger than the current size of the sequence, an error is returned<sup>7</sup>.

```
> a[3]:
Error, line 1: index out of range
```

The way Agenda outputs sequences can be changed by using the **settype** function.

```
> settype(a, 'duo');
> a:
duo(0, 1)
```

---

<sup>6</sup> The structure was originally introduced to efficiently support objects like complex numbers or numeric ranges including a flexible way to pretty print them at the console.

<sup>7</sup> The error message can be avoided by defining an appropriate metamethod.

The **gettype** function returns the new type you defined above as a string:

```
> gettype(a):
duo
```

If no user-defined type has been set, **gettype** returns **null**.

Once the type of a sequence has been set, the **typeof** function also returns this user-defined sequence type and will not return 'sequence'.

```
> typeof(a):
duo
```

This allows you to program special operations only applicable to certain types of sequences.

A user-defined type can be deleted by passing **null** as a second argument to **settype**.

```
> settype(a, null);

> typeof(a):
sequence
```

The **create seq** statement creates an empty sequence and optionally allows to allocate enough memory in advance to hold a given number of elements (which can be inserted later). Agena automatically will extend the sequence, if the predetermined number of items is exceeded.

```
create seq name1 [, seq name2, ...]
create seq name1(size1) [, seq name2(size2), ...]
```

Items can be added only sequentially. You may use the **insert** statement for this or the conventional indexing method.

```
> seq a(4);

> insert 1 into a;

> a[2] := 2;

> a:
seq(1, 2)
```

Note that if the index is larger than the number of items stored to it plus 1, Agena returns an error, since 'holes' in a sequence are not allowed. The next free position in a is at index 3, however a larger index is chosen in the next example.

```
> a[4] := 4
Error, line 1: index out of range
```

```
> a[3] := 3
```

Items can be deleted by setting their index position to **null**, or by applying **delete**, i.e. stating which items - not index positions - shall be removed. Note that all items to the right of the value deleted are shifted to the left, thus their indices will change.

```
> a[1] := null
```

```
> delete 2, 3 from a
```

```
> a:
seq()
```

If you assign a sequence to a variable, only a reference to the sequence is stored in the variable. Thus sequences behave the same way as tables and sets do, i.e. in a statement like `A := seq(); B := A`, A and B point to the same sequence in memory.

```
> A := seq()
```

```
> B := A
```

```
> A[1] := 10
```

```
> B:
seq(10)
```

The following operators, functions, and statements work on sequences:

Function	Description	Example
=	Equality check the Cantor way	a = b
==	strict equality check	a == b
<>	Inequality check	a <> b
<b>insert</b>	Inserts one or more elements.	insert 1 into a
<b>delete</b>	Deletes one or more elements.	delete 0, 1 from a
<b>copy</b>	Creates an exact copy of a sequence; deep copying is supported so that sequences inside sequences are properly treated.	b := copy a
<b>filled</b>	Checks whether a sequence has at least one item.	filled a
<b>in</b>	Checks whether an element is stored in the sequence, returns <b>true</b> or <b>false</b> .	0 in seq(1, 0)
<b>join</b>	Concatenates all strings in a sequence in sequential order.	join(a)
<b>size</b>	Returns the current number of items.	size a
<b>sort</b>	Sorts a sequence in place.	sort(a)
<b>type</b>	Returns the general type of a sequence, i.e. <b>sequence</b> .	type a
<b>typeof</b>	Returns the user-defined type of a sequence, or the basic type if no special type has been defined.	typeof a

Function	Description	Example
<b>unique</b>	Reduces multiple occurrences of an item in a sequence to just one.	<code>unique a</code>
<b>unpack</b>	Unpacks a sequence. See <b>unpack</b> in Chapter 7.1.	<code>unpack(a)</code>
<b>settype</b>	Sets a user-defined type for a sequence.	<code>settype(a, 'duo')</code>
<b>gettype</b>	Returns a user-defined type for a sequence.	<code>gettype(a)</code>
<b>setmeta</b>	Assigns a metatable to a sequence.	<code>setmeta(a, mtbl)</code>
<b>getmeta</b>	Returns the metatable stored to a sequence.	<code>getmeta(a)</code>

Table 11: Basic sequence procedures

## 4.12 More on the `create` statement

You cannot only initialise any number of tables with the **create** statement, but also dictionaries, sets, and sequences with only one call and in random order, so the following statement is valid;

```
> create table a, dict b(10), set c, seq d(100), table e(10);
> a, b, c, d, e:
[]      []      {}      seq()    []
```

## 4.13 Pairs

The structure which holds exactly two values of any type (including **null** and other pairs) is the *pair*. A pair cannot hold less or more values, but its values can be changed. Conceived originally to allow passing options in a more flexible way to functions, it is defined with the colon operator:

$item_1 : item_2$

```
> p := 1:2
> p:
1:2
```

The **left** and **right** operators provide the only read access to its left and right operands; the standard indexing method using indexed names is not supported:

$\text{left } [() \text{ pair } ()]$   
 $\text{right } [() \text{ pair } ()]$

```
> left(p):
1
> right p:
2
```

An operand of an already existing pair can be changed by assigning a new value to an indexed name, where the left operand is indexed with number 1, and the right operand with number 2:

```
> p[1] := 2;
```

```
> p[2] := 3;
```

As with sequences, you may define user-defined types for pairs with the **settype** function which also changes the way pairs are output.

```
> typeof(p):
```

```
pair
```

```
> settype(p, 'duo');
```

```
> p:
```

```
duo(2, 3)
```

```
> typeof(p):
```

```
duo
```

```
> gettype(p):
```

```
duo
```

The only other operators besides **left** and **right** that work on pairs are equality, inequality (= and <>), **type**, **typeof**, and **in**.

```
> p = 3:2:
```

```
false
```

With pairs consisting of numbers, the **in** operator checks whether a left-hand argument number is part of a closed numeric interval given by the given right-hand argument pair.

```
> 2 in 0:10:
```

```
true
```

```
> 's' in 0:10:
```

```
fail
```

As with all other structures, if you assign a pair to a variable, only a reference to the pair is stored in the variable. Thus in a statement like **A := a:b; B := A**, A and B point to the same pair.

Summary:

Function	Description	Example
<code>=</code>	Equality check	<code>a = b</code>
<code>&lt;&gt;</code>	Inequality check	<code>a &lt;&gt; b</code>
<code>in</code>	If the left operand <code>x</code> is a number and if the left and right hand side of the pair <code>a:b</code> are numbers, then the operator checks whether <code>x</code> lies in the closed interval <code>[a, b]</code> and returns <b>true</b> or <b>false</b> . If at least one value <code>x</code> , <code>a</code> , <code>b</code> is not a number, the operator returns <b>fail</b> .	<code>1.5 in 1:2</code>
<code>left</code>	Returns the left operand of a pair.	<code>left(a)</code>
<code>right</code>	Returns the right operand of a pair.	<code>right(a)</code>
<code>type</code>	With pairs, always returns <code>'pair'</code> .	<code>type(a)</code>
<code>typeof</code>	Returns either the user-defined type of the pair, or the basic type <code>('pair')</code> if no special type was defined for the pair.	<code>typeof(a)</code>
<code>settype</code>	Sets a user-defined type for a pair.	<code>settype(a, 'duo')</code>
<code>gettype</code>	Returns the user-defined type of a pair.	<code>gettype(a)</code>
<code>setmeta</code>	Sets a metatable to a pair.	<code>setmeta(p, mtbl)</code>
<code>getmeta</code>	Returns the metatable stored to a pair.	<code>getmeta(p)</code>

Table 12: Operators and functions applicable to pairs

#### 4.14 Other types

For threads, userdata, and lightuserdata please refer to the Lua 5.1 documentation.

## Chapter Five

# Control

## 5 Control

### 5.1 Conditions

Depending on a given condition, Agena can alternatively execute certain statements with either the **if** or **case** statement.

#### 5.1.1 if Statement

The **if** statement checks a condition and selects one statement from many listed. Its syntax is as follows:

```

if condition1 then
    statements1
[elif condition2 then
    statements2]
[else
    statements3]
fi
    
```

The condition may always evaluate to one of the Boolean values **true**, **false**, or **fail**, or to **any other** value.

The **elif** and **else** clauses are optional. While more than one **elif** clause can be given, only one **else** clause is accepted. An if statement may include one or more **elif** clauses and no **else** clause.

If an **if** or **elif** condition results to **true** or any other value except **false**, **fail**, or **null**, its corresponding **then**-clause is executed. If any condition results to **false**, **fail**, or **null**, the **else** clause is executed if present, otherwise Agena proceeds with the next statement following the **if** statement.

Examples:

The condition **true** is always true, so the string 'yes' is printed.

```

> if true then
>     print('yes')
> fi;
yes
    
```

In the following statement, the condition evaluates to **false**, so nothing is printed:

```

> if 1 <> 1 then
>     print('this will never be printed')
> fi;
    
```

An **if** statement with an **else** clause:

```
> if false then
>   print('this will never be printed')
> else
>   print('this will always be printed')
> fi;
this will always be printed
```

An **if** statement with an **elif** clause:

```
> if 1 = 2 then
>   print('this will never be printed')
> elif 1 < 2 then
>   print('this will always be printed')
> fi;
this will always be printed
```

An **if** statement with **elif** and **else** clauses:

```
> if 1 = 2 then
>   print('this will never be printed')
> elif 1 < 2 then
>   print('this will always be printed')
> else
>   print('neither will this be printed')
> fi;
this will always be printed
```

### 5.1.2 is Operator

The **is** operator checks a condition and returns the respective expression.

```
is condition then
    expression1
else
    expression2
si
```

This means that the result is *expression*<sub>1</sub> if *condition* is **true** or any other value except **false**, **fail**, or **null**; and *expression*<sub>2</sub> otherwise.

Example:

```
> x := is 1=1 then true else false si:
true
```

which is the same as:

```
> if 1=1 then
>   x := true
> else
>   x := false
> fi;
```

The **is** operator only evaluates the expression that it will return. Thus the other expression which will not be returned will never be checked for semantic correctness, e.g. out-of-range string indices, etc. You may nest **is** operators.

### 5.1.3 case Statement

The **case** statement facilitates comparing values and executing corresponding statements.

```
case name
  of value11 [, value12] then statements1
  [of value21 [, value22] then statements2]
  [of ...]
  [else statementsk]
esac
```

```
> a := 'k';

> case a
>   of 'a', 'e', 'i', 'o', 'u', 'y' then result := 'vowel'
>   else result := 'consonant'
> esac;

> result:
consonant
```

You can add as many **of .. then** statements as you like. Fall through is not supported. This means that if one **then** clause is executed, Agenda will not evaluate the following **of** clauses and will proceed with the statement right after the closing **esac** keyword.

## 5.2 Loops

Agenda has two basic forms of control-flow statements that perform looping: **while** and **for**, each with different variations.

### 5.2.1 while-Loops

A **while** loop first checks a condition and if this condition is **true** or any other value except **false**, **fail**, or **null**, it iterates the loop body again and again as long as the condition remains true. If the condition is **false**, **fail** or **null**, no further iteration is done and control returns to the statement following right after the loop body.

If the condition is **false**, **fail**, or **null** from the start, the loop is not executed at all.

```
while condition do
  statements
od
```

The following statements calculate the largest Fibonacci number less than 1000.

```
> a := 0; b := 1;

> while b < 1000 do
>   c := b;
>   b := a + b;
>   a := c
> od;

> c:
987
```

The following loop will never be executed since the condition is **false**:

```
> while false do
>   print('this will never be printed')
> od;
```

A variation of **while** is the **do .. as** loop which checks a condition at the end of the iteration and thus will always be executed at least once.

```
do
  statements
as condition
```

```
> c := 0;

> do
>   inc c
> as c < 10;

> c:
10
```

**for** loops are used if the number of iterations is known in advance. There are **for/to** loops for numeric progressions, and **for/in** loops for table and string iterations.

### 5.2.2 for/to loops

Let us first consider numeric **for/to** loops which use numeric values for control:

```
for [external] name [from start] [to stop] [by step] do
  statements
od
```

*name*, *start*, *stop*, and *step* are all numeric values or must evaluate to numeric values.

The statement at first sets the variable *name* to the numeric value of *start*. *name* is called the *control* or *loop variable*. If *start* is not given, the start value is +1. If stop is not given, the last iteration value is **infinity**<sup>8</sup>.

It then checks whether *start* ≤ *stop*. If so, it executes *statements* and returns to the top of the loop, increments *name* by *step* and then checks whether the new value is less or equal *stop*. If so, *statements* are executed again. If *step* is not given, the control variable is always incremented by +1.

```
> for i from 1 to 3 by 1 do
>   print(i, i^2, i^3)
> od;
1      1      1
2      4      8
3      9     27
```

```
> for i to 3 do
>   print(i, i^2, i^3)
> od;
1      1      1
2      4      8
3      9     27
```

The loop control variable is local to the loop body, so it cannot be used after looping completed. However, if you put the **external** keyword in front of the control variable, you will have access to the control variable after looping completed and may use its value in subsequent statements. This rule applies only to for/from/to-loops with or without a **while** extension. Note that if you use the **external** option within procedures, you usually want to declare the loop control variable as local, otherwise it will be treated as a global variable.

```
> for external i to infinity while math.fact(i) < 1k do od
> i:
7
```

When using the **external** switch the following rules apply to the value of the control variable after leaving the loop:

1. If the loop terminates normally, i.e. if it iterates until its stop value, then the value of the control variable is its stop value *plus* the step size.
2. If the loop is left prematurely by executing a **break** statement<sup>9</sup> within the loop, or if a for/while loop is terminated because the **while** condition evaluated to **false**, then the control variable is set to the loop's last iteration value before quitting the loop. There will be no increment with the loop's step size.

---

<sup>8</sup> These loops do not run infinitely, but stop at the numeric value of the C constant HUGE\_VAL which varies among systems.

<sup>9</sup> See chapter 5.2.8 for more information in the **break** statement.

Loops can also count backwards if the step size is negative:

```
> for i from 2 to 1 by -1 do
>   print(i)
> od
2
1
```

A special form is the **to .. do** loop which does not feature a control variable and iterates exactly *n* times.

```
> to 2 do
>   print('iterating')
> od
iterating
iterating
```

### 5.2.3 for/in Loops for Tables

are used to traverse tables<sup>10</sup>, strings, sets, and sequences. Let us first concentrate on table iteration.

```
for key, value in tbl do
  statements
od
```

The loop iterates over all key~value pairs in table *tbl* and with each iteration assigns the respective key to *key*, and its value to *value*.

```
> a := [4, 5, 6]

> for i, j in a do
>   print(i, j)
> od
1      4
2      5
3      6
```

There are two variations: When putting the keyword **keys** in front of the control variable, the loop iterates only on the keys of a table:

```
for keys key in tbl do
  statements
od
```

---

<sup>10</sup>To be more general, for/in loops iterate over functions called iterators. Check out the Lua documentation for more information.

Example:

```
> for keys i in a do
>   print(i)
> od
1
2
3
```

The other variation iterates on the values of a table only:

```
for value in tbl do
  statements
od
```

```
> for i in a do
>   print(i)
> od
4
5
6
```

The control variables in **for/in** loops are always local to the body of the loop, the **external** switch is not supported. You may assign their values to other variables if you need them later.

You should never change the value of the control variables in the body of a loop - the result would be undefined. Use the **copy** operator to safely traverse any structure if you want to change, add, or delete its entries.

#### 5.2.4 for/in Loops for Sequences

All of the features explained in the last subchapter are applicable to sequences, as well.

#### 5.2.5 for/in Loops for Strings

If you want to iterate over a string character by character from its left to its right, you may use a for/in loop as well. All of the variations except the **external** option mentioned in the previous subchapter are supported.

```
for key, value in string do statements od

for value in string do statements od

for keys value in string do statements od
```

The following code converts a word to a sequence of abstract vowel, ligature, and consonant placeholders and also counts their respective occurrence:

```
> str := 'æfter';
> result := '';
> c, v, l -> 0;

> for i in str do
>   case i
>     of 'a', 'e', 'i', 'o', 'u' then
>       result := result .. 'V';
>       inc v
>     of 'å', 'æ', 'ø', 'ö' then
>       result := result .. 'L';
>       inc l
>     else
>       result := result .. 'C'
>       inc c
>   esac
> od;

> print(result, v .. ' vowels', l .. ' ligatures', c .. ' consonants');
LCCVC          1 vowels          1 ligatures          3 consonants
```

### 5.2.6 for/in Loops for Sets

All **for** loop variations are supported with sets, as well. The only useful one, however, is the following:

```
> sister := {'swistar', 'sweastor', 'svasar', 'sister'}
> for i in sister do print(i) od;
svasar
swistar
sweastor
sister
```

You may try the other loop alternatives to see what happens.

### 5.2.7 for/while Loops

All flavours of for loops can be combined with a **while** condition. As long as the **while** condition is satisfied, the **for** loop iterates. To be more precise, before Agena starts the first iteration of a loop or continues with the next iteration, it checks the while condition to be true or any other value except **false**, **fail**, or **null**.

```
for [external] i [from a] to b [by step] while condition do statements od
for [key,] value in struct while condition do statements od
for keys key in struct while condition do statements od
for [key,] value in string while condition do statements od
for keys key in string while condition do statements od
```

An example:

```
> for x to 10 while ln(x) <= 1 do print(x, ln(x)) od
1      0
2      0.69314718055995
```

Regardless of the value of the **while** condition, the loop control variables are always initiated with the start values: with for/to loops, *a* is assigned to *i* (or 1 if the **from** clause is not given); *key* and/or *value* are assigned with the first item in the table, set, or sequence *struct* or the first character in string *string*.

### 5.2.8 Loop Interruption

Agenda features two statements to manipulate loop execution. Both are applicable to all loop types.

The **skip** statement causes another iteration of the loop to begin at once, thus skipping all of the loop statements following it.

The **break** statement quits the execution of the loop entirely and proceeds with the next statement right after the end of the loop.

```
> for i to 5 do
>   if i = 3 then skip fi;
>   print(i)
>   if i = 4 then break fi;
> od;
1
2
4
```

This is equivalent to the following statement:

```
> for i to 5 while i < 5 do
>   if i = 3 then skip fi;
>   print(i)
> od;
1
2
4

> a := 0;

> while true do
>   inc a
>   if a > 5 then break fi
>   if a < 3 then skip fi
>   print(a)
> od
3
4
5
```

## Chapter Six

# Programming

## 6 Programming

Writing effective code in a minimum amount of time is one of the key features of Agenda. Programs are usually represented as procedures. The words `procedure` and `function` are used synonymously in this text.

### 6.1 Procedures

In general, procedures cluster a sequence of statements into abstract units which then can be repeatedly invoked.

Writing procedures in Agenda is quite simple:

```
procname := proc([par1 [::type1] [, par2 [::type2], ...] ) [is]
    [local name1 [, name2, ...]];
    statements
end
```

All the values that a procedure shall process are given as *parameters* *par*<sub>1</sub>, etc. A function may have no, one, or more parameters. A parameter may be succeeded by the name of a type (see Chapter 6.7). The **is** keyword is optional.

A procedure usually uses local variables which are private to the procedure and cannot be used by other procedures or on the Agenda interactive level.

Global variables are supported in Agenda, as well. All values assigned on the interactive level are global, and you can also create global variables within a procedure. The values of global variables can be accessed on the interactive level and within any procedure.

A procedure may call other functions or itself. A procedure may even include definitions of further local or global procedures.

The result of a procedure is returned using the **return** keyword which may be put anywhere in the procedure body.

```
return value [, value2, ...]
```

As you can see, you may not only return a single result, but also multiple ones.

Also, a procedure might not necessarily return anything - in this case do not use the **return** statement at all. If no **return** statement is given, the procedure does not even return the **null** value.

The following procedure computes the factorial of an integer<sup>11</sup>:

```
> fact := proc(n) is
>   # computes the factorial of an integer n
>   if n < 0 then return fail
>   elif n = 0 then return 1
>   else return fact(n-1)*n
>   fi
> end;
```

It is called using the syntax:

$$\text{funcname}([arg_1 [, arg_2, \dots]])$$

```
> fact(4):
24
```

where the first parameter is replaced by the first argument  $arg_1$ , the second parameter is substituted with  $arg_2$ , etc.

## 6.2 Local Variables

The function above does not need local variables as it calls itself recursively. However, with large values for  $n$ , the large number of unevaluated recursive function calls will ultimately lead to stack overflows. So we should use an iterative algorithm to compute the factorial and store intermediate results in a local variable.

A local variable is known only to the respective procedure and the block where it has been declared. It cannot be used in other procedures, the interactive Agena level, or outside the block where it has been declared.

A local variable can be declared explicitly anywhere in the procedure body, but at least before its first usage. If you do not declare a variable and assign values later to this variable, then it is global. Note that control variables in **for** loops are always implicitly declared local if the **external** switch is not used, so we do not need to explicitly declare them.

Local declarations come in different flavours:

```
local name1 [, name2, ...]
local name1 [, name2, ...] := value1 [, value2, ...]
local name1 [, name2, ...] -> value
local enum name1 [, name2, ...] [from value]
```

In the first form,  $name_1$ , etc. are declared local.

---

<sup>11</sup>The library function **math.fact** is much faster.

In the second and third form, *name<sub>1</sub>*, etc. are declared local followed by initial assignments of values to these names.

In the last form, *name<sub>1</sub>*, etc. are declared local with a subsequent enumeration of those names.

Let us write a procedure to compute the factorial using a for loop. To avoid unnecessary loop iterations when the intermediate result has become so large that it cannot be represented as a finite number, we also add a clause to quit loop iteration in such cases.

```
> fact := proc(n) is
>   if n < 0 then return fail fi;
>   local result := 1;
>   for i from 1 to n do
>     result := result * i
>     if result = infinity then break fi
>   od;
>   return result
> end;

> fact(10):
3628800
```

result has been declared local so it has no value at the interactive level.

```
> result:
null
```

### 6.3 Global Variables

Global variables are visible to all procedures and the interactive level, such that their values can be queried and altered everywhere.

Using global variables is not recommended. However, they are quite useful in order to have more control on the behaviour of procedures. For example, you may want to define a global variable `_EnvMoreInfo` that is checked in your procedures in order to print or not to print information to the user.

Global variables can be indicated with the **global** keyword. This is optional, however, and only serves documentary purposes.

```
> fact := proc(n) is
>   global _EnvMoreInfo;
>   if n < 0 then return fail fi;
>   local result := 1;
>   for i from 1 to n do
>     result := result * i
>     if result = infinity then
>       if _EnvMoreInfo then print('Overflow !') fi;
>       break
>     fi
>   od;
>   return result
> end;
```

We must assign `_EnvMoreInfo` a value in order to get a warning message at runtime.

```
> _EnvMoreInfo := true;

> fact(10000):
Overflow !
infinity
```

## 6.4 Changing Parameter Values

You can assign new values to procedure parameters within a procedure. Thus, an alternative to the **abs** operator might be:

```
> myAbs := proc(x) is
>   if x < 0 then
>     x := -x
>   fi;
>   return x
> end;

> myAbs(-1):
1
```

## 6.5 Optional Arguments

A function does not have to be called with exactly the number of parameters given at procedure definition. You may optionally pass less or more values. If no value is passed for a parameter, then it is automatically set to **null** at function invocation. If you pass more arguments than there are actual parameters, excess arguments are ignored.

For example, we can avoid using a global variable to get a warning message by passing an optional argument instead.

```
> fact := proc(n, warning) is
>   if n < 0 then return fail fi;
>   local result := 1;
>   for i from 1 to n do
>     result := result * i
>     if result = infinity then
>       if warning then print('Overflow !') fi;
>       break
>     fi
>   od;
>   return result
> end;

> fact(10000):
infinity
```

The option should be any value other than **null**, **false**, or **fail** to get the effect.

```
> fact(10000, true):
Overflow !
infinity
```

A variable number of arguments can be passed by indicating them with a question mark in the parameter list and then querying them with the **varargs** system table in the procedure body.

```
> varadd := proc(?) is
>   local result := 0;
>   for i to size varargs do
>     inc result, varargs[i]
>   od;
>   return result
> end;

> varadd(1, 2, 3, 4, 5):
15
```

You may determine the number of arguments *actually* passed in a procedure call by querying the system variable **nargs** inside the respective procedure. A variant of the above procedure might thus be:

```
> varadd := proc(?) is
>   local result := 0;
>   for i to nargs do
>     inc result, varargs[i]
>   od;
>   return result
> end;

> varadd(1, 2, 3, 4, 5):
15
```

Let us build an extended square root function that either computes in the real or complex domain. By default, i.e. if only one argument is given, the real domain is taken, otherwise you may explicitly set the domain using a pair as a second argument.

```
> xsqrt := proc(x, mode) is
>   if nargs = 1 or mode = 'domain':'real' then
>     return sqrt(x)
>   elif mode = 'domain':'complex' then
>     return sqrt(x + 0*I)
>   else
>     return fail
>   fi
> end;

> xsqrt(-2):
undefined

> xsqrt(-2, 'domain':'real'):
undefined
```

If the left-hand value of the pair in a function call shall denote a string, you can spare the single quotes around the string by using the ~ token which converts the left-hand name to a string.

```
> xsqrt(-2, domain ~ 'complex'):
1.4142135623731*I
```

## 6.6 Passing Options in any Order

We can combine the `varargs` facility with the usage of pairs in order to pass one or more optional arguments in any order.

```
> f := proc(?) is
>   local bailout, iterations := 2, 128; # default values
>   for i to nargs do
>     case left(varargs[i])
>       of 'bailout' then
>         bailout := right(varargs[i]);
>       of 'iterations' then
>         iterations := right(varargs[i]);
>       else
>         print 'unknown option'
>       esac
>   od;
>   print('bailout = ' .. bailout, 'iterations = ' .. iterations)
> end;

> f();
bailout = 2      iterations = 128

> f('bailout':10);
bailout = 10     iterations = 128

> f('iterations':32, 'bailout':10);
bailout = 10     iterations = 32
```

Again, the single quotes around the name of the option (left-hand side of the pair) can be spared by using the `~` token which converts the given name to a string.

```
> f(bailout ~ 10, iterations ~ 32);
bailout = 10     iterations = 32
```

## 6.7 Type Checking & Error Handling

Although Agena is untyped, in many situations you may want to check the type of a certain value passed to a function. Agena has three facilities for this:

1. The **type** operator determines the type of its argument.
2. A type can be optionally specified in the parameter list of a procedure by means of the preceding `::` token so that it will be checked at procedure invocation.
3. The **try** statement checks whether one or more values are of a specific type.

The language also provides the **error** handling function that interrupts the execution of a procedure and prints an error message if given.

The following types are available in Agena:

```
boolean, complex, lightuserdata, null, number, pair, procedure,
sequence, set, string, table, thread, userdata.
```

These names are reserved keywords, but evaluate to strings so that they can be compared with the result of the **type** operator that returns the type of a value as a string.

```
> type(1):
number

> fact := proc(n) is
>   if type(n) <> number then
>     error('number expected')
>   fi;
>   if n < 0 then return null
>   elif n = 0 then return 1
>   else return fact(n-1)*n
>   fi
> end;

> fact('10'):
Error: number expected
      in function fact, line 3
```

You may also optionally specify types in the parameter list of a procedure by using double colons:

```
> fact := proc(n::number) is
>   if n < 0 then return null
>   elif n = 0 then return 1
>   else return fact(n-1)*n
>   fi
> end;

> fact('10'):
Error: invalid type for argument #1: expected number, got string.
```

This form of type checking is more than twice as fast as the if/type/error combination. If the argument is of the correct type, Agenda executes the procedure, otherwise it issues an error. Agenda will also return an error if the argument is not given:

```
> fact()
missing argument #1 (type number expected).
```

Another efficient way of type checking is provided by the **try** statement.

```
try name1 [, name2, ...] as typename1, [name3 [, name4, ...] as typename2, ...]

      try name1 [, name2, ...] as typename1 else errorstring1
      [, name3 [, name4, ...] as typename2 else errorstring2, ...]
```

In the first form, a standard error message is displayed and further computation stops. In the second form, a user defined error text is printed and execution of the function is interrupted.

```

> fact := proc(n) is
>   try n as number;
>   if n < 0 then return null
>   elif n = 0 then return 1
>   else return fact(n-1)*n
>   fi
> end;

> fact('10'):
Error, line 2: expected number, got string for argument #1.
  in function fact, line 2

> fact := proc(n) is
>   try n as number else 'bad value for argument';
>   if n < 0 then return null
>   elif n = 0 then return 1
>   else return fact(n-1)*n
>   fi
> end;

> fact('10'):
Error, line 2: for argument #1: bad value for argument
  in function fact, line 2

```

Note that the **type** operator, the double colon functionality, and the **try** statement only check for basic types. If you want to check user-defined types for procedures, tables, sequences, sets, and pairs, you should use the **typeof** operator.

## 6.8 Multiple Returns

As stated before, a procedure can return no, one, or more values. There are two ways to use these multiple returns in subsequent statements.

Consider the **strings.find** library function. It searches for a pattern in a string and returns the first and the final position of the pattern as two numbers.

```

> strings.find('Wulfila', 'ila'):
5          7

```

If you assign the return to only one variable, e.g.

```

> m := strings.find('Wulfila', 'ila'):
5

```

the second return is lost, so enter:

```

> m, n := strings.find('Wulfila', 'ila');

> m:
5

> n:
7

```

A function may also return a variable number of values. To store any of these returns for later access, just put the returns in a sequence or table:

```
> seq(strings.find('Wulfila', 'ila')):
seq(5, 7)
```

## 6.9 Shortcut Procedure Definition

If your procedure consists of exactly one *expression*, then you may use an abridged syntax if the procedure does not include statements such as **if .. then**, **for**, **insert**, etc.

$$<< [( [par_1 :: type_1] [, par_2 :: type_2], \dots ] [] ] \rightarrow expr >>$$

As you see, optional types can be specified in the parameter section.

Let us define a simple factorial function.

```
> fact := << (x::number) -> exp(gammaln(x+1)) >>
> fact(4):
24
```

Brackets around the parameters are optional, even if you specify types.

```
> isInteger := << x -> int(x) = x >>
> isInteger(1):
true
> isInteger(1.5):
false
```

Passing optional arguments using the ? notation is supported. In this case, use the **varargs** table as described above.

## 6.10 User-Defined Procedure Types

The **settype** function allows to group procedures  $proc_1, proc_2, \dots$ , by giving them a specific type (passed as a string) just as it does with sequences, tables, sets, and pairs.

$$\text{settype}(proc_1 [, proc_2, \dots], 'your\_proctype')$$

The **typeof** operator returns the user-defined type of an object as a string. If no special type has been defined, it returns its basic type. The latter also applies to data types where **settype** cannot set user-defined types.

`typeof(proc1)`

The **type** operator does not return the user-defined type even if it is set, it will always return the basic type of an object.

```
> f := << x -> 1 >>
> settype(f, 'constant')
> typeof(f):
constant
> type(f):
procedure
```

### 6.11 Scoping Rules

In Agena, variables live in blocks or `scopes`. A block may contain one or more other blocks. A local variable is visible only to the block in which it has been declared and to all blocks that are part of this block. Thus, variables declared local in inner blocks are not accessible to the outer blocks.

Procedures, **if**- and **case**-statements, **while**-, **do**- and **for**-loops create blocks.

Variables declared local within procedures are only visible in these procedures.

Variables declared local in the **then** clauses of an **if**-statement live only in the respective **then** part. The same applies to variables declared local in **else** clauses.

```
> f := proc(x) is
>   if x > 0 then
>     local i := 1; print('inner', i)
>   else
>     local i := 0; print('inner', i)
>   fi;
>   print('outer', i) # i is not visible
> end;

> f(1);
inner    1
outer    null
```

Variables declared local in **for**- or **while**-loops are only accessible in the bodies of these loops. The loop control variables of **for/to**- and **for/in**-loops are implicitly declared local to the respective loop bodies, with the exception of the **external** facility of **for/to** loops which is described in the next subchapter.

```
> f := proc(x) is
>   while x < 2 do
>     local i := x
>     inc x
>     print('inner', i)
>   od;
>   print('outer', i) # i is not visible
```

```
> end;

> f(1);
inner    1
outer    null
```

A special scope can be declared with the **scope** and **epocs** statements:

```
scope
  declarations & statements
epocs
```

The next example demonstrates how it works:

```
> f := proc() is
>   local a := 1;
>   scope
>     local a := 2;
>     writeline('inner a: ', a);
>   epocs;
>   writeline('outer a: ', a);
> end;

> f()
inner a: 2
outer a: 1
```

## 6.12 Loops in Procedures

As already noted, the control variable of a for/to loop is only local to the loop itself - but if you use the **external** keyword in the loop declaration, you will have access to it after execution of the loop completed. Make sure that in this case, you define the control variable local.

```
> mandelbrot := proc(x, y, iter, radius) is
>   local i, c, z;
>   z := x!y;
>   c := z;
>   for external i from 0 to iter while abs(z) < radius do
>     z := z^2 + c
>   od;
>   return i # return the last iteration value
> end;
```

The procedure counts the number of iterations a complex value  $z$  takes to escape a given radius by applying it to the formula  $z = z^2 + c$ . Since the loop control variable  $i$  has been declared external, it can be used in the **return** statement.

The following example demonstrates that local variables are bound to the block in which they have been declared.

```
> f := proc() is
>   local i;
>   for external i to 3 do
>     local j;
```

```

>      for external j to 3 do od;
>      print(i, j)
>    od;
>    print(i, j)
> end;

> f()
1      4
2      4
3      4
3      null

```

## 6.13 Packages

### 6.13.1 Writing a New Package

Let us write a small utilities package called `helpers` including only one main and one auxiliary function. The main function shall return the number of digits of an integer.

Package procedures are usually stored to a table, so we first create a table called `helpers`. After that, we assign the procedure `ndigits` and the auxiliary `isInteger` function to this table.

```

> create table helpers;

> helpers.isInteger := << x -> int(x) = x >>; # aux function

> helpers.ndigits := proc(n::number) is
>   if not helpers.isInteger(n) then
>     error('argument is not an integer')
>   fi;
>   if n = 0 then
>     return 1
>   else
>     return entier(ln(abs(n))/ln(10) + 1);
>   fi;
> end;

```

Now we can use our new package.

```

> helpers.ndigits(0):
1

> helpers.ndigits(-10):
2

> helpers.ndigits(.1):
Error: argument is not an integer
      in function ndigits, line 4

```

To save us a lot of typing, we can assign a short name to this table procedure.

```

> ndigits := helpers.ndigits;

> ndigits(999):
3

```

Save the code listed above to a file called `helpers.agn` in a subfolder called `helpers` in the Agenda main directory. In order to use the package again after you have restarted Agenda, use the **run** function.

```
> restart;

> run `d:/agenda/helpers/helpers.agn

> helpers.ndigits(10):
2
```

You may print the contents of the package table at any time:

```
> helpers:
[isInteger ~ procedure(0044A6E0), ndigits ~ procedure(0044A850)]
```

### 6.13.2 The with Function

The **with** function besides loading the package in a convenient way, automatically assigns short names to all or a user-defined set of package procedures so that you may use the shortcuts instead of the fully written function names.

```
> restart;

> with `helpers
isInteger, ndigits

> isInteger(1); # same as helpers.isInteger(1)
```

You may also want **with** to print a start-up notice at every package invocation if you assign a string to the table field `packagename.initstring`. Put the following code into the `helpers.agn` file, save the file and restart Agenda:

```
> helpers.initstring := 'helpers v1.0 as of December 24, 2007\n';

> restart;

> with `helpers
helpers v1.0 as of December 24, 2007

isInteger, ndigits
```

Since you may not want that short names are set for auxiliary functions, you can put the names of all procedures for which short names shall be assigned as strings into the `packagename.loaded` table using the **register** function. Insert the following line to your `helpers.agn` file at any position:

```
> register(helpers, `ndigits);
```

The contents of the `helpers.agn` file should finally look like this:

```
create table helpers;
```

```

helpers.initstring := 'helpers v1.0 as of December 24, 2007\n';

helpers.isInteger := << x -> int(x) = x >>; # aux function

helpers.ndigits := proc(n) is
  try n as number;
  if not helpers.isInteger(n) then
    error('argument is not an integer')
  fi;
  if n = 0 then
    return 1
  else
    return entier(ln(abs(n))/ln(10) + 1);
  fi;
end;

register(helpers, 'ndigits');

```

Save the file again and restart Agena.

```

> restart;

> with `helpers
helpers v1.0 as of December 24, 2007

ndigits

```

If your package includes an initialisation routine, then it will be run after the package has been found successfully. The name of the initialisation routine must be of the form ``packagename.init``, e.g.:

```

> helpers.init := proc() is
>   writeline('I am run')
> end;

```

## 6.14 Remember tables

Agena features remember tables which if present hold the results of previous calls to Agena or API C procedures or contain a list of predefined results, or both. If a function is called again with the same argument or the same arguments, then the corresponding result is returned from the table, and the procedure body is not executed. Remember tables are called *rtables* or *rotables* for short.

There are two types of remember tables:

- Standard Remember Tables, called ``rtables``, that can be automatically updated by a call to the respective function; they may be initialised with a list of precomputed results (but do not need to).
- Read-Only Remember Tables, called ``rotables``, that cannot be updated by a call to the respective function. Rotables should be initialised with a list of precomputed results.

### 6.14.1 Standard Remember Tables

A standard remember table is suited especially for recursively defined functions. It may slow down functions, however, if they have remember tables but do not rely much on previously computed results.

By default, no procedure contains a remember table, they must explicitly be created with the **rinit** function and optionally filled with default values with the **rset** function. Since those functions are very basic, a more convenient facility is the **remember** function which will exclusively be used in this chapter.

In order for an rtable to be automatically updated, the respective function must return its result with the **return** statement (which may sound profane). If a function is called with arguments that are not already known to the remember table, then the **return** statement adds these arguments and the corresponding result or results to the rtable.

Two examples: We want to define a function  $f(x) = x$  with  $f(0) = \text{undefined}$ .

First the function is defined:

```
> f := << x -> x >>;
```

Only after the function has been created, the rtable (short for remember table) can be set up. The **remember** function can be used to initialise rtables, explicitly set predefined values to them, and add further values later in a session.

```
> remember(f, [0~undefined]);
```

The rtable has now been created and a default entry included in it so that calling f with argument 0 returns **undefined** and not 0.

```
> f(1):
1
```

```
> f(0):
undefined
```

If the function is redefined, the rtable is destroyed, so you may have to initialise it again.

Fibonacci numbers can be implemented recursively and run with astonishing speed using rtables.

```
> fib := proc(n) is
>   assume(n >= 0);
>   return fib(n-2) + fib(n-1)
> end;
```

The call to **assume** assures that n is always non negative and serves as an `emergency brake` in case the remember table has not been set up properly.

The `rtable` is being created with two default values:

```
> remember(fib, [0~1, 1~1]);
```

If we now call the function,

```
> fib(50):
20365011074
```

the contents of the `rtable` will be:

```
1 ~ [1~1]
2 ~ [1~1]
3 ~ [1~2]
4 ~ [1~3]
5 ~ [1~5]
6 ~ [1~8]
7 ~ [1~13]
8 ~ [1~21]
9 ~ [1~34]
...
```

If a function has more than one parameter or has more than one return, **remember** requires a different syntax: The arguments and the returns are still passed as key~value pairs. However, the arguments are passed in one table, and the returns are passed in another table.

```
> f := proc(x, y) is
>   return x, y
> end;

> remember(f, [[1, 2] ~ [0, 0]]);

> a, b := f(1, 2);

> a:
0

> b:
0
```

Please check Chapter 7.1 for more details on their use.

### 6.14.2 Read-Only Remember Tables

If you do not want that a function updates its remember table each time it is called with new arguments and results, you may use a read-only remember table, called ``rotable`` for short. Rotables are initialised with a list of precomputed results.

The function itself cannot implicitly enter new entries to its remember table via the **return** statement; it can only do so via a call to the `rset` function (or a utility that is based on `rset`). This gives you total control of the contents and the amount of data stored in a remember table - and thus on the speed of your procedure.

Assume you want to define a procedure that computes factorials  $n!$ , and that does not compute the results for  $n < 11$ , but retrieves the results from an rotatable instead.

A function might look like this:

```
> fact := proc(x::number) is
>   if int(x) = x then # is x an integer and nonnegative ?
>     return exp(gammln(x+1))
>   else
>     return undefined
>   fi
> end;
```

The **defaults** function can set up the rotatable and enter precomputed values into it.

```
> # set precompiled results for 0! to 10! to fact

> defaults(fact, [
>   0~1.0000000000000000e+00, 1.0000000000000000e+00,
>   2.0000000000000000e+00, 6.0000000000000000e+00,
>   2.4000000000000000e+01, 1.2000000000000000e+02,
>   7.2000000000000000e+02, 5.0400000000000000e+03,
>   4.0320000000000000e+04, 3.6288000000000000e+05,
>   3.6288000000000000e+06]);
```

The factorial function is significantly faster when called with arguments that are in the rotatable than if there would be no such value cache, because it would have to compute the results instead of just reading them.

Let us look into the remember table:

```
> defaults(fact):
[[2] ~ [2], [1] ~ [1], [8] ~ [40320], [9] ~ [362880], [10] ~ [3628800],
[0] ~ [1], [4] ~ [24], [5] ~ [120], [6] ~ [720], [3] ~ [6], [7] ~ [5040]]
```

You can also easily add further argument ~ result pairs with the defaults function:

```
> defaults(fact, [11 ~ 39916800]); defaults(fact):
[[2] ~ [2], [1] ~ [1], [8] ~ [40320], [9] ~ [362880], [10] ~ [3628800], [0]
~ [1], [11] ~ [39916800], [4] ~ [24], [7] ~ [5040], [6] ~ [720], [3] ~ [6],
[5] ~ [120]]
```

A read-only remember table can be deleted by passing **null** as a second argument to **defaults**.

### 6.14.3 Functions for Remember Tables

For completeness, all basic functions which work on rtables are the following:

Procedure	Details
<b>rinit(f)</b>	Initialises a standard remember table for the function $f$ .
<b>hashtable(f)</b>	Checks whether procedure $f$ possesses an rtable.
<b>rget(f)</b>	Returns the rtable of function $f$ .

Procedure	Details
<b>rinit</b> (f)	Initialises a read-only remember table for the function $\varepsilon$ .
<b>rset</b> (f, argument, return) <b>rset</b> (f, [arguments], [returns])	Adds function argument(s) and the corresponding return(s) to the rtable of procedure $\varepsilon$ .
<b>rdelete</b> (f)	Deletes the rtable of function $\varepsilon$ entirely. If you want to use a new rtable with the function, you have to initialise it with <b>rinit</b> again.
<b>rwrite mode</b> (f)	Returns true if a function has a standard remember table, false if it has a read-only remember table, and fail if it has no remember table at all.

Table 13: Functions for remember tables

### 6.15 Overloading Operators with Metamethods

One of the many useful functions inherited from Lua 5.1 are metamethods which provide a means to apply existing operators to tables, sets, sequences, and pairs.

For example, complex arithmetic could be entirely implemented with metamethods so that you can use already existing symbols and keywords such as **+** or **abs** with complex values and do not have to learn names of new functions<sup>12</sup>.

This method of defining additional functionality to existing operators is also known as ‘overloading’.

Adding such functionality to existing operators is very easy. As an example, we will define a constructor to produce complex values and three metamethods for adding complex values with the **+** token, determining their absolute value with the standard **abs** operator, and pretty printing them at the console.

At first, lets store a complex value  $z = x + yi$  to a sequence of size 2. The real part is saved as the first value, the imaginary part at the second.

```
> cmplx := proc(a::number, b::number) is
>   create local seq r(2);
>   insert a, b into r;
>   return r
> end;
```

To define a complex value, say  $z = 0 + i$ , just call the constructor:

```
> cmplx(0, 1):
seq(0, 1)
```

The output is not that nice, so we would like Agena to print `cmplx(0, 1)` instead of `seq(0, 1)`. This can be easily done with the **settype** function:

---

<sup>12</sup>For performance reasons, complex arithmetic has been built directly into the Agena kernel.

```
> cmplx := proc(a::number, b::number) is
>   create local seq r(2);
>   insert a, b into r;
>   settype(r, 'cmplx');
>   return r
> end;

> cmplx(0, 1):
cmplx(0, 1)
```

Adding two complex values does not work yet, for we have not yet defined a proper metamethod.

```
> cmplx(0, 1) + cmplx(1, 0):
Error, line 1: attempt to perform arithmetic on a sequence value
```

Metamethods are defined using dictionaries, called `metatables`. Their keys, which are always strings, denote the operators to be overloaded, the corresponding values are the procedures to be called when the operators are applied to tables, sets, sequences (which are used in this example), or pairs. See the Appendix A2 for a list of all available method names. To overload the plus operator use the `\_\_add` string.

Assign this metamethod to any name, `cmplx_mt` in this example.

```
> cmplx_mt := [
>   '__add' ~ proc(a, b) is
>               return cmplx(a[1]+b[1], a[2]+b[2])
>           end
> ]
```

Next, we must attach this metatable `cmplx_mt` to the sequence storing the real and imaginary parts with the **setmetatable** function. We have to extend the constructor by one line, the call to **setmetatable**:

```
> cmplx := proc(a::number, b::number) is
>   create local seq r(2);
>   insert a, b into r;
>   settype(r, 'cmplx');
>   setmetatable(r, cmplx_mt);
>   return r
> end;
```

Try it:

```
> cmplx(0, 1) + cmplx(0, 1):
cmplx(0, 2)
```

Add a new method to calculate the absolute value of complex numbers by overloading the **abs** operator.

```
> cmplx_mt.__abs := << (a) -> math.hypot(a[1], a[2]) >>;
```

The metatable now contains two methods.

```
> cmplx_mt:
__add ~ procedure(003FE3E8)
__abs ~ procedure(0046CE80)

> z := cmplx(1, 1)
```

```
> abs(z):
1.4142135623731
```

It would be quite fine if complex values would be output the usual way using the standard  $x + yi$  notation. This can be done with the `'__tostring'` method which must return a string.

```
> cmplx_mt.__tostring := proc(z) is
>   return if z[2]<0 then z[1]..z[2]..'i' else z[1]..'+'..z[2]..'i' si;
> end;

> z:
1+1i
```

To avoid using the `cmplx` constructor in calculations, we want to define the imaginary unit  $i = 0+i$  and use it in subsequent operations. Before assigning the  $i$  unit, we have to add a metamethod for multiplying a number with a complex number.

```
> cmplx_mt.__mul := proc(a, b) is
>   if typeof(a) = 'cmplx' and typeof(b) = 'cmplx' then
>     return cmplx(a[1]*b[1]-a[2]*b[2], a[1]*b[2]+a[2]*b[1])
>   elif type(a) = number and typeof(b) = 'cmplx' then
>     return cmplx(a*b[1], a*b[2])
>   fi
> end;
```

and also extend the metamethod for complex addition.

```
> cmplx_mt.__add := proc(a, b) is
>   if typeof(a) = 'cmplx' and typeof(b) = 'cmplx' then
>     return cmplx(a[1]+b[1], a[2]+b[2])
>   elif type(a) = number and typeof(b) = 'cmplx' then
>     return cmplx(a+b[1], b[2])
>   fi;
> end;

> i := cmplx(0, 1);

> a := 1+2*i:
1+2i
```

Until now, the real and imaginary parts can only be accessed using indexed names, say `z[1]` for the real part and `z[2]` for the imaginary part. A more convenient - albeit not that performant - way to use a notation like `z.re` and `z.im` in both read and write operations is provided by the `'__index'` and `'__writeindex'` metamethods, respectively.

The `__index` metamethod for *reading* values from a structure works as follows:

- If the structure is a table, then the metamethod is called if the call to an indexed name results to **null**.
- If the structure is a set, then the metamethod is called if the call to an indexed name results to **false**.
- If the structure is a sequence, then the metamethod is called if the call to an indexed name would result to an index-out-of-range error.

The `__writeindex` metamethod for *writing* values to a structure works as follows:

- If the structure is a table, sequence or pair, then the metamethod is always called.
- The metamethod is also supported by the **insert** statement.

The respective procedures assigned to the `__index` and `__writeindex` keys of a metatable should not include calls to indexed names, for in some cases this would lead to stack overflows due to recursion (the respective metamethod is called again and again). Instead, use the **rawget** function to directly read values from a structure, and the **rawset** function to enter values into a structure.

Let us first define a global mapping table for symbolic names to integer keys:

```
> cmplx_indexing := {'re'~1, 'im'~2};
```

Now let us define the two new metamethods. Both will be capable to accept expressions like `a.re` and `a[1]`. In the following read procedure the argument `x` represents the complex value, and the argument `y` is assigned either the string `'re'` or `'im'`. Thus, `cmplx_indexing['re']` will evaluate to the index 1, and `cmplx_indexing['im']` to index 2.

```
> cmplx_mt.__index := proc(x, y) is # read operation
>   if type(y) = string then # for calls like `a.re` or `a.im`
>     return rawget(x, cmplx_indexing[y])
>   else
>     return rawget(x, y)      # for calls like `a[1]` or `a[2]`
>   fi
> end;
```

In the write procedure, argument `x` will hold the complex value, `y` will be either `'re'` or `'im'`, and `z` is assigned the component - a rational number -, i.e. `x.re := z` or `x.im := z`.

```
> cmplx_mt.__writeindex := proc(x, y, z) is # write operation
>   if type(y) = string then
>     rawset(x, cmplx_indexing[y], z)
>   else
>     rawset(x, y, z) # for assignments like `a[1] := value`
>   fi
> end;
```

You can now use the new methods.

```

> a:
1+2i

> a.re:
1

> a.im := 3

> a:
1+3i

```

### 6.16 Extending built-in Functions

You may redefine existing built-in functions if you want to change their behaviour or extend its features. You can either write a completely new replacement from scratch or use the original function in your modified version. Your new procedure can then be called with the same name as the original one.

Note that only Agena functions written in C or in the language itself can be redefined, and that operators cannot.

In Agena, each mathematical function  $f$  works as follows: if a number  $x$ , which by definition represents a value in the real domain, is passed to them, then the result  $f(x)$  will also be in the real domain. If  $x$  is a complex value, then the result will be in the complex domain.

Suppose that you want to automatically switch to the complex domain if a function value in the real domain could not be determined, i.e. if  $f(x) = \text{undefined}$ . An example is:

```

> math.arcsin(-2):
undefined

```

On the interactive level enclose the new procedure definition with the **scope** and **epocs** keywords. This is necessary because on the interactive level, each statement entered at the prompt has its own scope and thus local variables cannot be accessed in the next statement.

The new function definition might be:

```

> scope
>
>   # save the original function in a `hidden` variable
>   local oldarcsin := math.arcsin;
>
>   math.arcsin := proc(x) is # new definition
>     local result := oldarcsin(x);
>     if result = undefined then # switch to complex domain
>       result := oldarcsin(x+0*I)
>     fi;
>     return result
>   end;
>
> epocs;

```

The original function `math.arcsin` is stored to the local `oldarcsin` variable so that the user can no longer directly access it.

```
> math.arcsin(-2):
-1.5707963267949+1.3169578969248*I
```

If you wish to permanently use your redefined functions, just put them into the `agenda.ini` file, located in the `lib` folder of your Agenda installation. Since files have their own ``scope``, the `scope` and `epocs` keywords are no longer needed (but can be left in the file).

## 6.17 Closures: Procedures that Remember their State

A procedure can remember its state. This state is represented by the function's internal variables which can survive and keep their values even after the call to the procedure completed.

So with a successive call to the same procedure, it can access these values and use them in the current call again.

Let us define an iterator function that successively returns an element of a sequence:

```
> traverse := proc(o::table) is
>   local count := 0;
>   return proc() is
>     inc count;
>     return o[count]
>   end
> end;
```

The `traverse` procedure is called a factory for it returns the closure as a function which we assign to the name `iterator`. The `iterator` function remembers its state and can be called like ``normal`` functions:

```
> iterator := traverse(['a', 'b', 'c']);

> iterator():
a
```

What happened ? The call to `traverse` with the table `['a', 'b', 'c']` as its only argument initialised the variable `count` and assigned it to 0. The table you passed is also stored to the closure's internal state. With the first call to `iterate`, `count` was incremented from 0 to 1, followed by the return of the first element in the table.

```
> iterator():
b

> iterator():
c
```

Since the table has no more elements left (`count = 4`), it now returns `null`.

```
> iterator():
null
```

You can define more than one closure with a factory at the same time, each being completely independent from the others:

```
> iterator2 := traverse(['a', 'b', 'c']);

> iterator2():
a

> iterator2():
b

> iterator3 := traverse(['a', 'b', 'c']);

> iterator3():
a
```

## 6.18 File I/O

Agena features various functions to deal with files, to read lines and write values to them. Most of the functions come from Lua. All the functions processing files are included in the **io** package.

### 6.18.1 Reading Text Files

One of the most useful functions to read in a text file line by line is the **io.lines** procedure which accepts the name of the file to be read as a string. They are usually used in **for** loops. The line read is stored to the loop key, the loop value is always **null**.

```
> for i, j in io.lines('d:/adena/lib/adena.ini') do
>   print(i, j)
> od
execute := os.execute;      null
getmeta  := getmetatable;   null
setmeta  := setmetatable;   null
```

### 6.18.2 Writing Text Files

To write numbers or strings into a file, we must first create it with the **io.open** function. The second argument tells Agena to open the file in ``write`` mode.

```
> file := io.open('d:/file.text', 'w');
```

**io.open** returns an integer, a so-called file handle. File handles are used in many IO functions, e.g. the **write** procedure.

```
> io.write(file, 'I am a text.');
```

After all values have been written, the file must be closed with **io.close**.

```
> io.close(file);
```

Tables, sets, or sequences cannot be written directly to files, they must be iterated using loops so that their keys and values - which must be numbers or strings - can be accessed and stored to the file thereafter. The same applies to pairs: use the **left** and **right** operators to write their components.

The following statements write all keys and values to the file. The keys and values are separated by a pipe '|', and a newline is inserted after each key~value pair has been added. Note that you can mix numbers and strings.

```
> a := [10, 20, 30];  
  
> file := io.open('d:/table.text', 'w');  
> for i, j in a do  
>   io.write(file, i, '|', j, '\n')  
> od;  
  
> io.close(file);
```

## Chapter Seven

# Standard Libraries

## 7 Standard Libraries

The standard libraries taken from the Lua 5.1 distribution provide useful functions that are implemented directly through the C API. Some of these functions provide essential services to the language (e.g., **next** and **getmetatable**); others provide access to "outside" services (e.g., I/O); and others could be implemented in Agena itself, but are quite useful or have critical performance requirements that deserve an implementation in C (e.g., **sort**).

The following text is based on Chapter 5 of the Lua 5.1 manual and includes all the new operators, functions, and packages provided by Agena.

Lua functions which were deleted from the code are not described. References to Lua were not deleted from the original text. If an explanation mentions Lua, then the description also applies to Agena.

All libraries are implemented through the official C API and are provided as separate C modules. Currently, Agena has the following standard libraries:

- the basic library,
- package library,
- string library,
- table library,
- mathematical library,
- two input and output libraries,
- operating system library,
- debug facilities.

Except for the basic and the package libraries, each library provides all its functions as fields of a global table or as methods of its objects. Agena operators have directly built into the kernel (the Virtual Machine), so they are not part of any library.

### 7.1 Basic Functions

The basic library provides some core functions to Agena. If you do not include this library in your application, you should check carefully whether you need to provide implementations for some of its facilities.

#### **abs (x)**

If *x* is a number, the **abs** operator will return the absolute value of *x*. Complex numbers are supported.

If *x* is a Boolean, it will return 1 for **true**, 0 for **false**, and -1 for **fail**.

If *x* is null, **abs** will return -2.

If *x* is a string of only one character, **abs** will return the ASCII value of the character as a number. If *x* is the empty string or longer than length 1, the function returns fail.

#### **anames ([option])**

Returns all global names that are assigned values in the environment. If called without arguments, all global names are returned. If *option* is given and *option* is a string denoting a type (e.g. 'boolean', 'table', etc.), then all variables of that type are returned.

The function is written in the Agena language and included in the `library.agn` file.

#### **assigned (v)**

This Boolean operator checks whether any value different from **null** is assigned to the expression *v*. If *v* is already a constant, i.e. a number or a string, the operator always returns **false**. If *v* evaluates to a constant, the operator returns **true**.

See also: **isnull**.

#### **assume (v [, message])**

Issues an error when the value of its argument *v* is **false** (i.e., **null** or **false**); otherwise, returns all its arguments. *message* is an error message; when absent, it defaults to "assumption failed".

#### **attrib (o)**

With the table *o*, returns a new table with

- the current maximum number of key~value pairs allocable to the array and hash parts of *o*; in the resulting table, these values are indexed with keys 'array\_allocated' and 'hash\_allocated', respectively,
- the number of key~value pairs actually assigned to the respective array and hash sections of *o*; in the resulting table, these values are indexed with keys 'array\_assigned' and 'hash\_assigned',
- an indicator 'array\_hashholes' stating whether the array part contains at least one hole.

With the set *o*, returns a new table with

- the current maximum number of items allocable to the set; in the resulting table, this value is indexed with the key 'hash\_allocated'.
- the number of items actually assigned to *o*; in the resulting table, this value is indexed with the key 'hash\_assigned'.

With the sequence *o*, returns a new table with

- the maximum number of items assignable; in the resulting table, this value is indexed with the key 'maxsize'. If the number of entries is not restricted, 'maxsize' is **infinity**.
- the current number of items actually assigned to `o`; in the resulting table, this value is indexed with the key 'size'.

With the function `o` returns a new table with

- the information whether the function is a C or an Agenda function. In the resulting table, this value is indexed with the key 'c';
- whether a function contains a remember table, indicated by the C 'rtableWritemode', where the entry **true** indicates that it is an rtable (which is updated by the **return** statement), where **false** indicates that it is an rotable (which cannot be updated by the **return** statement), and where **fail** indicates that the function has no remember table at all.

**bye**

Quits the Agenda session. No argument or brackets are needed.

**clear v1 [, v2, ...]**

Deletes the values in variables `v1`, `v2`, ..., and performs a garbage collection thereafter in order to clear the memory occupied by these values.

**concat (obj [, sep [, i [, j]]])**

Returns `obj[i]..sep..obj[i+1] ... sep..obj[j]`, where `obj` is either a table or sequence of strings. The default value for `sep` is the empty string, the default for `i` is 1, and the default for `j` is the length of the table. If `i` is greater than `j`, returns the empty string. The empty string is also returned, if `obj` consists entirely of non-strings.

Use the **toString** function if you want to concatenate other values than strings, e.g.:

```
> concat(map(toString, [1, 2, 3])):
123
```

**defaults (func)**

**defaults (func, tab)**

**defaults (func, null)**

Administrates read-only remember tables of functions. As it works exactly like the **remember** function, except that it creates remember tables that cannot be updated by the **return** statement, please refer to the description of the **remember** function for further details.

**error** (message [, level])

Terminates the last protected function called and returns `message` as the error message. Function **error** never returns.

Usually, `error` adds some information about the error position at the beginning of the message. The `level` argument specifies how to get the error position. With level 1 (the default), the error position is where the `error` function was called. Level 2 points the error to where the function that called `error` was called; and so on. Passing a level 0 avoids the addition of error position information to the message.

**\_G**

A global variable (not a function) that holds the global environment (that is, `_G._G = _G`). Agena itself does not use this variable; changing its value does not affect any environment, nor vice-versa. (Use **selfenv** to change environments.)

**filled** (obj)

This Boolean operator checks whether a table, set, or sequence `obj` contains at least one item and returns **true** if so; otherwise it returns **false**.

**gc** ([opt [, arg]])

This function is a generic interface to the garbage collector. It performs different functions according to its first argument, `opt`:

- **'stop'**: stops the garbage collector.
- **'restart'**: restarts the garbage collector.
- **'collect'**: performs a full garbage-collection cycle (if no option is given, this is the default action).
- **'count'**: returns the total memory in use by Agena (in Kbytes).
- **'step'**: performs a garbage-collection step. The step 'size' is controlled by `arg` (larger values mean more steps) in a non-specified way. If you want to control the step size you must experimentally tune the value of `arg`. Returns **true** if the step finished a collection cycle.
- **'setpause'**: sets `arg/100` as the new value for the *pause of the collector*.
- **'setstepmul'**: sets `arg/100` as the new value for the *step multiplier of the collector*.

**getfenv** (f)

Returns the current environment in use by the function. `f` can be an Agena function or a number that specifies the function at that stack level: Level 1 is the function calling **getfenv**. If the given function is not an Agena function, or if `f` is 0, **getfenv** returns the global environment. The default for `f` is 1.

### **globals (f)**

Determines<sup>13</sup> whether function  $f$  includes global variables (names which have not been defined local).

### **getmeta (object)**

#### **getmetatable (object)**

If `object` does not have a metatable, returns **null**. Otherwise, if the `object`'s metatable has a `'__metatable'` field, returns the associated value. Otherwise, returns the metatable of the given `object`.

### **gettype (o)**

Returns the type - set with **settype** - of a function, sequence, set, or pair `o` as a string. If no user-defined type has been set, or any other data type has been passed, null is returned.

See also: **settype**.

### **has (s, x)**

Checks whether the structure `s` (a table, set, sequence, or pair) contains element `x`. With tables, both indices (keys) and entries are scanned (if the index is a set, table, pair, or sequence, the index is not scanned, however). With sequences, only the entries (not the keys) are scanned. With pairs, both the left and the right item is scanned. The function performs a deep scan so that it can find elements in deeply nested structures.

The function is written in the Agena language and included in the `library.agn` file.

### **hasrtable (f)**

Checks whether function  $f$  has a remember table. It returns **true** if it has got one, and **false** otherwise.

### **isnull (v)**

This Boolean operator checks whether an expression `v` evaluates to **null**. If `v` is a constant, i.e. a number or a string, the operator always returns **false**.

See also: **assigned**.

---

<sup>13</sup>Note that the function not always returns all global names.

**left (p)**

Returns the left operand of the pair *p*.

See also: **right**.

**load (func [, chunkname])**

Loads a chunk using function *func* to get its pieces. Each call to *func* must return a string that concatenates with previous results. A return of **null** (or no value) signals the end of the chunk.

If there are no errors, returns the compiled chunk as a function; otherwise, returns **null** plus the error message. The environment of the returned function is the global environment.

*chunkname* is used as the chunk name for error messages and debug information.

**loadClib (packagename, path)**

Loads the C library *packagename* (with extension *.so* in UNIX or *.dll* in Windows) residing in the folder denoted by *path*. *path* must be the name of the folder where the C library is stored, and not the absolute path name of the file. The function returns **true** in case of success and **false** otherwise.

**loadfile ([filename])**

Similar to **load**, but gets the chunk from file *filename* or from the standard input, if no file name is given.

**loadstring (string [, chunkname])**

Similar to **load**, but gets the chunk from the given string. To load and run a given string, use the idiom

```
assume(loadstring(s))()
```

**map (f, o [, ...])**

This operator maps a function *f* to all the values in table, set, sequence, or pair *o*. The function must return only one value. The type of return is the same as of *o*. If *o* has metamethods, the return will also have them. If *o* is a sequence or pair, its special type if present is copied, as well.

If function *f* has only one argument, then only the function and the structure *o* must be passed to **map**. If the function has more than one argument, then all arguments *except the first* are passed right after the name of the table or set.

Examples:

```
> map( << x -> x^2 >>, [1, 2, 3] ):
```

```
1 ~ 1
2 ~ 4
3 ~ 9
```

```
> map( << (x, y) -> x > y >>, [-1, 0, 1], 0 ): # 0 for y
1 ~ false
2 ~ false
3 ~ true
```

See also: **zip**, **select**, **remove**.

**mapto**set (function, obj [, ...])

Maps a function to all the values in table or sequence **obj** and returns a set. Metamethods if existing are not copied. See **map** for further information.

**max** (t [, 'sorted'])

Returns the maximum of all numeric values in table or sequence **t**. If the option 'sorted' is passed then the function assumes that all values in **t** are sorted in ascending order and returns the last entry.

See also: **min**.

**min** (t [, 'sorted'])

Returns the minimum of all numeric values in table or sequence **t**. If the option 'sorted' is passed then the function assumes that all values in **t** are sorted in ascending order and returns the first entry.

See also: **max**.

**next** (o [, index])

Allows a program to traverse all fields of a table or all items of a set or sequence **o**. With strings, it iterates all its characters. Its first argument is a table, set, string, or sequence and its second argument is an index in the structure.

With tables or sequences, **next** returns the next index of the structure and its associated value. When called with **null** as its second argument, **next** returns an initial index and its associated value. When called with the last index, or with **null** in an empty structure, **next** returns **null**.

With sets, **next** returns the next item of the set twice. When called with **null** as its second argument, **next** returns the initial item twice. When called with the last index, or with **null** in an empty set, **next** returns **null**.

With strings, **next** returns the position of the respective character (a positive integer) and the character. When called with **null** as its second argument, **next** returns the first character. When called with the last index, **next** returns **null**.

If the second argument is absent, then it is interpreted as **null**. In particular, you can use `next(t)` to check whether a table or set is empty. However, it is recommended to use the **filled** operator for this purpose.

The order in which the indices are enumerated is not specified, *even for numeric indices*. The same applies to set items.

The behaviour of `next` is undefined if, during the traversal, you assign any value to a non-existent field in the structure. With tables, you may however modify existing fields. In particular, you may clear existing table fields.

#### **ops (index, ...)**

If `index` is a number, returns all arguments after argument number `index`. Otherwise, `index` must be the string `'#'`, and **ops** returns the total number of extra arguments it received. The function is useful for accessing multiple returns (e.g. `ops(n, ?)`).

#### **pcall (f, arg1, ...)**

Calls function `f` with the given arguments in *protected mode*. This means that any error inside `f` is not propagated; instead, `pcall` catches the error and returns a status code. Its first result is the status code (a boolean), which is true if the call succeeds without errors. In such case, `pcall` also returns all results from the call, after this first result. In case of any error, `pcall` returns **false** plus the error message.

#### **pointer (o)**

Converts `o` to a generic C pointer (void\*) and returns the result as a string. `o` may be a userdata, table, set, sequence, pair, thread, function, or complex value; otherwise, **pointer** returns **fail**. Different objects will give different pointers.

#### **print (...)**

Receives any number of arguments, and prints their values to `stdout`, using the **toString** function to convert them to strings. **print** is not intended for formatted output, but only as a quick way to show a value, typically for debugging. For formatted output, use **strings.format**.

In Agena, **print** also prints the *contents* of tables and nested tables to `stdout` if no `__toString` metamethods are assigned to them. The same applies to sets and sequences. After **\_EnvMore** number of lines, **print** halts for the user to press any key for further output. Press 'q', 'Q', or the Escape key to quit. The default for **\_EnvMore** is 40 lines, but you may change this value in the Agena session or in the `adena.ini` file.

If the environment variable **\_EnvLongTable** is set to **true**, then the each key~value pair is printed on a separate line.

You may change the way **print** formats objects by changing the respective **\_EnvPrint** functions in the `library.agn` file. See Appendix A5 for further details.

**rawequal (v1, v2)**

Checks whether `v1` is equal to `v2`, without invoking any metamethod. Returns a boolean.

**rawget (obj, index)**

Gets the real value of `obj[index]`, without invoking any metamethod. `obj` must be a table, set, sequence, or pair; `index` may be any value.

**rawset (obj, index, value)**

**rawset (obj, value)**

In the first form, sets the real value of `obj[index]` to `value`, without invoking any metamethod. `obj` must be a table, sequence, or pair, `index` any value different from **null**, and `value` any value.

In the second form, the function inserts `value` into the next free position in the given structure `obj`. `obj` can be a table, set, or sequence.

This function returns `obj`.

**rdelete (func)**

Deletes the remember table or read-only remember table of procedure `func` entirely. The function returns **null**.

**read (fn)**

Reads an object stored in the binary file denoted by file name `fn` and returns it.

The function is written in the Agena language and included in the `library.agn` file.

See also: **save**, **debug.doubleendiantest**.

**readlib (packagename)**

Loads and runs packages stored to agn text files (with filename `packagename.agn`) or binary C libraries (`packagename.so` in UNIX, `packagename.dll` in Windows).

The function first tries to find the binary C library which must reside in the `/lib` folder of the Agena directory. If it finds it, it loads and runs the library and proceeds with the next step.

Next, the function tries to locate an Agena text file library in the folder `/packagename` of the Agena directory and loads, runs it when found and quits thereafter. Otherwise

it tries to find the library in the `/lib` folder in the Agena directory, loads and runs it when found.

Make sure that in your operating system, you have set the environment variable `AGENAPATH` to the main folder where Agena resides and that the path does not end with a slash. In Win32, you may set the variable with the following statement:

```
SET AGENAPATH=d:/adena
```

The function returns **true** if the package has been successfully loaded and executed, or **false** if an error occurred.

You may also pass a complete file name (with or without path) to the function. In this case the given file is loaded and executed.

See also: `run`, `with`.

```
register (pkgname, name1 [, name2, ...])
```

Defines short names for a package. It enters the strings `name1` (and `name2`, etc. if given) into the table `pkgname.loaded`, so that if you initialise a package **with** the `with` function, those names `namek` can be used as short names for package functions instead of the fully written function names.

So, instead of later calling a function by "`pkgname.name(arguments)`" you may use the shortcut "`name(arguments)`". See **with** for more details.

This is short for insert `name1 [, name2, ...]` into `pkgname.loaded`. If a name is already included in the table, `register` does not add it.

```
_RELEASE
```

A global variable that holds a string containing the language name, the current interpreter main version, the subversion, and the patch level. The format of this variable is: `'AGENA >> <version>.<subversion>.<patchlevel>'`.

See also: `_EnvRelease`.

```
remember (func)
```

```
remember (func, tab)
```

```
remember (func, null)
```

Administrates remember tables.

In the first form, the remember table stored to procedure `func` is returned. See **rget** for more information.

In the second form, **remember** adds the arguments and returns contained in table `tab` to the remember table of function `func`. If the remember table of `func` has not

been initialised before, **remember** creates it. If there are already values in the remember table, they are kept and not deleted.

If `func` has only one argument and one return, the function arguments and returns are passed as key~value pairs in table `tab`.

If `func` has more than one argument, the arguments are passed in a table. If `func` has more than one return, the returns are passed in a table, as well.

Valid calls are:

```
remember(f, [0 ~ 1]);           # one argument 0 & one return 1
remember(f, [[1, 2] ~ [3, 4]]); # two arguments 1, 2 & two returns 3, 4
remember(f, [1 ~ [3, 4]]);      # one argument 1 & two returns 3, 4
remember(f, [[1, 2] ~ 3]);      # two arguments 1, 2 & one return 3
```

In the third form, by explicitly passing **null** as the second argument, the remember table of `func` is destroyed and a garbage collection run to free up space occupied by the former rtable.

**remember** always returns **null**. It is written in the Agena language and included in the `library.agn` file.

See chapter 6.14 for examples. See also: **defaults**.

**remove (f, o [, ...])**

Returns all values in table, set, or sequence `o` that do not satisfy a condition determined by function `f`, as a new table, set, or sequence. The type of return is determined by the type of second argument.

If the function has only one argument, then only the function and the table/set/sequence are passed to **remove**.

```
> remove(<< x -> x > 1 >>, [1, 2, 3]):
1 ~ 1
```

If the function has more than one argument, then all arguments *except the first* are passed right after the name of the table or set.

```
> remove(<< x, y -> x > y >>, [1, 2, 3], 1): # 1 for y
1 ~ 1
```

See also: **select**, **map**, **zip**.

**restart**

Restarts an Agena session. No argument is needed.

During start-up, Agena stores all initial values, e.g. package tables assigned, in a global variable called **\_origG**. Tables are copied, too, so their contents cannot be

altered in a session.

If the Agena session is restarted with **restart**, all values in the Agena environment are unassigned including the environment variable **\_G**, but except of **\_origG** and **\_EnvAgenaPath**. Then all entries in **\_origG** are read and assigned to the new environment. After this, the library base file `agena.lib` and thereafter the initialization file `agena.ini` - if present - are read and executed. Finally, **restart** runs a garbage collection.

The return of the function is **false** if evaluation of **\_origG** failed because it is no longer a table (which should never happen). Otherwise, the return is **true**.

**rget (func [, option])**

Returns the contents of the current remember table or read-only remember table of procedure `func`. If any value for `option` is given, the internal remember table including all the hash values are returned.

```
> fib := proc(n) is
>   assume(n >= 0);
>   return fib(n-2) + fib(n-1)
> end;

> remember(fib, [0~0, 1~1]);

> rget(fib):
[[0] ~ [0], [1] ~ [1]]
```

You cannot destroy the internal remember table by changing the table returned by **rget**.

**right (p)**

Returns the right operand of the pair `p`.

See also: **left**.

**rinit (func)**

Creates a remember table (an empty table) for procedure `func`. The procedure must have been written in the Agena language; reminisce that `rtables` for C API functions are not supported and that in these cases the function quits with an error.

If there is already a remember function for `func`, it is overwritten. **rinit** returns **null**.

**roinit (func)**

Creates a read-only remember table (an empty table) for procedure `func`, which may be either a C function or an Agena procedure.

If there is already a remember function for `func`, it is overwritten. **roinit** returns **null**.

**rset (func, arguments, returns)**

The function adds one (and only one) function-argument-and-returns `pair` to the already existing remember table or read-only remember table of procedure `func`. `arguments` must be a table array, `returns` must also be a table array. If the argument(s) already exist(s) in the remember table, then the corresponding result(s) are replaced with `returns`.

Given a function `f := << x -> x >>` for example, valid calls are:

```
rset(f, [1], [2]); rset(f, [1, 2], [2]); rset(f, [1], [1, 2]).
```

**run (filename)**

Opens the named file and executes its contents as a chunk. When called without arguments, **run** executes the contents of the standard input (stdin). Returns all values returned by the chunk. In case of errors, **run** propagates the error to its caller (that is, **run** does not run in protected mode).

See also: **readlib**, **with**.

**save (o, fn)**

Saves an object `o` of any type into a binary file denoted by file name `fn`.

The function is written in the Agena language and included in the `library.agn` file.

See also: **read**, **debug.doubleendiantest**.

**select (f, o [, ...])**

Returns all values in table, set, or sequence `o` that satisfy a condition determined by function `f`. The type of return is determined by the type of second argument.

If the function has only one argument, then only the function and the object are passed to **select**.

```
> select(<< x -> x > 1 >>, [1, 2, 3]):
2 ~ 2
3 ~ 3
```

If the function has more than one argument, then all arguments except *the first* are passed right after the name of the object.

```
> select(<< x, y -> x > y >>, {1, 2, 3}, 1): # 1 for y
3
2
```

If present, the function also copies the metatable of `o` to the new structure.

See also: **remove**, **map**, **zip**.

**setfenv** (*f*, *table*)

Sets the environment to be used by the given function. *f* can be an Agena function or a number that specifies the function at that stack level: Level 1 is the function calling **setfenv**. **setfenv** returns the given function.

As a special case, when *f* is 0 **setfenv** changes the environment of the running thread. In this case, **setfenv** returns no values.

**setmeta** (*s*, *metatable*)

**setmetatable** (*s*, *metatable*)

Sets the metatable for the given table, set, sequence, or pair *s*. (You cannot change the metatable of other types from Agena, only from C.) If *metatable* is **null**, removes the metatable of the given table. If the original metatable has a `'__metatable'` field, raises an error.

This function returns *s*.

**settype** (*o* [, ...], *str*)

**settype** (*o* [, ...], **null**)

In the first form the function sets the type of one or more procedures, sequences, tables, sets, or pairs *o* to the name denoted by string *str*. **gettype** and **typeof** will then return this string when called with *o*.

In the second form, by passing the **null** constant, the user-defined type is deleted, and **gettype** thus will return **null** whereas **typeof** will return the basic type of *o*.

If *o* has no `__tostring` metamethod, then Agena's pretty printer outputs the object in the form `str..'(..<elements>..')` instead of the standard `'seq('..<elements>..')` Or `'<element>:<element>'` string.

Note that the `try` statement does not handle user-defined types.

See also: **gettype**.

**size** (*v*)

With tables, the operator returns the number of key~value pairs in table *v*.

With sets and sequences, the operator returns the number of items in *v*. With strings, the operator returns the number of characters in string *v*, i.e. the length of *v*.

**sort (o [, comp])**

Sorts table or sequence elements in a given order, in-place, from `o[1]` to `o[n]`, where `n` is the length of the structure. If `comp` is given, then it must be a function that receives two structure elements, and returns **true** when the first is less than the second (so that not `comp(a[i+1], a[i])` will be **true** after the sort). If `comp` is not given, then the standard operator `<` is used instead.

The sort algorithm is not stable; that is, elements considered equal by the given order may have their relative positions changed by the sort.

**time ()**

Returns the time till start-up in seconds as a number.

**toSeq (s)**

If `s` is a string, the function will split it into its characters and return them in a sequence with each character in `s` as a sequence value, and in the same order as the characters in `s`.

If `s` is a table, the function puts all its values - but not its keys - into a sequence.  
If `s` is a set, the function puts all its items into a sequence.

**toTable (s)**

If `s` is a string, the function splits it into its characters, and returns them in a table with each character in `s` as a table value in the same order as the characters in `s`.

If `s` is a sequence or set, the function converts it into a table.

**type (v)**

This operator returns the basic type of its only argument, coded as a string. The possible results of this function are 'null' (a string, not the value **null**), 'number', 'string', 'boolean', 'table', 'set', 'sequence', 'pair', 'complex', 'procedure', 'thread', and 'userdata'.

If `v` is a sequence, pair, or procedure with a user-defined type, then **type** always returns the basic type, i.e. 'sequence' or 'pair', or 'procedure', respectively.

See also: **typeof**.

**typeof (v)**

This operator returns the user-defined type - if it exists - of its only argument, coded as a string.

A special type can be defined for procedures, pairs, sets, and sequences with the **settype** function. If there is no user-defined type for *v*, then the basic type is returned, i.e. 'null' (a string, not the value **null**), 'number', 'string', 'boolean', 'table', 'set', 'sequence', 'pair', 'complex', 'procedure', 'thread', and 'userdata'.

See also: **type**.

**unpack** (list [, i [, j]])

Returns the elements from the given table or sequence. This function is equivalent to

```
return list[i], list[i+1], ..., list[j]
```

except that the above code can be written only for a fixed number of elements. By default, *i* is 1 and *j* is the length of the list, as defined by the length operator.

**used** ()

Returns the total memory in use by Agena in Kbytes. It is a shortcut for `gc('count')`. The function is written in the Agena language and included in the `library.agn` file.

**userinfo** (fn, level [, ...])

Writes information to the user of a procedure *fn* depending on the given *level*, an integer. The information to be printed is passed as the third, etc. arguments and may be either numbers or strings.

At first the procedure should be registered in the global **infolevel** table along with a *level* (an integer) indicating the **infolevel** setting at which information will be printed. If you do not enter an entry for the function to the **infolevel** table, then nothing is printed.

```
> f := proc(x) is
>   userinfo(f, 1, 'this is a primary info to the user: ', x);
>   userinfo(f, 2, 'this is an additional info to the user: ', x)
> end;
```

If the *level* argument to **userinfo** is equal or less than the **infolevel** table setting, then the information is printed, otherwise nothing is printed.

```
> infolevel[f] := 2;

> f('hello !');
this is a primary info to the user:   hello !
this is an additional info to the user: hello !
```

Now the **infolevel** is decreased such that less information will be output.

```
> infolevel[f] := 1;
```

```
> f('hello !');
this is a primary info to the user:      hello !
```

**whereis** (*o*, *x*)

Returns the indices for a given value *x* in table or sequence *o* as a new table or sequence, respectively. The function is written in the Agena language and included in the `library.agn` file.

See also: `tables.indices`.

**with** (*packagename*, [*key1*, *key2*, ...])

Assigns short names to package procedures such that:

```
name := packagename.name
```

The function works as follows:

- In both forms, **with** first tries to load and run the respective Agena package. The package may reside in a text file with file suffix `.agn`, or in a C dynamic link library with file suffix `.so` in UNIX and `.dll` in Windows, or both in a text file and in a dynamic link library. In a first step, the function looks into the `lib` folder of the main Agena library to find the package files. If it did not find it in the `lib` folder, it switches to the `packagename` folder in the main Agena directory and tries to load it from there. Note that the package files must reside either in the `lib` or in the `packagename` folder.
- If either the Agena library or the C library could not be found, **with** proceeds without errors. If both are missing, an error is returned.
- Next, **with** tries to find a package initialisation procedure. If a procedure named `<packagename>.init` is present in your package then it is executed if the package has been found successfully.
- In the first form, if only the string `packagename` is given, short names to all functions residing in the global table `packagename` are created.

You may optionally assign short names to either all or only specific procedures. If you only want define short names to some of the functions, define a table `<packagename>.loaded` and include the respective function names as strings. If the table `<packagename>.loaded` is not present, **with** assigns short names to all keys in `<packagename>`.

Note that if `packagename.name` is not of type procedure, a short name is not created for this object.

If there is a table `<packagename>.loaded`, then **with** prints only those values included in this table. If `<packagename>.loaded` does not exist, all keys in `<packagename>` are printed.

An example: If your package is called ``agenapackage``, then the short names to be printed are included in:

```
agenapackage.loaded := ['run', 'dosomething'];
```

If you would like to display a welcome message, put it into the string `<packagename>.initstring`. It is displayed with an empty line before and after the text. An example:

```
agenapackage.initstring := 'agenapackage v0.1 for Agena as of \
December 24, 2008\n';
```

- In the second form, you may specify which short names are to be assigned by passing them as further arguments in the form of strings. Contrary to the first form, short names are also created for tables stored to table `<packagename>`.

As opposed to the first version, **with** does not print any short names or welcome messages on screen.

- Further information applying to both forms:

The function returns **a table of all short names assigned** .

If the global environment variable `_EnvWithVerbose` is set to **false**, no messages are displayed on screen except in case of errors. If it is set to any other value or **null**, a list of all the short names loaded and a welcome message is printed.

If a short name has already been assigned, a warning message is printed. If a short name is protected (see table `_EnvProtected`), it cannot be overwritten by **with** and a proper message is displayed on screen. You can control which names are protected by modifying the contents of `_EnvProtected`.

In Windows, make sure that you have set the environment variable `AGENAPATH` to the main folder where Agena resides and that the path does not end with a slash. You may set the variable with the following statement, e.g.:

```
SET AGENAPATH=d:/adena
```

if Agena is installed in the `d:\adena` folder. In UNIX, Agena by default searches in the `/usr/adena` folder if `AGENAPATH` has not been set.

Note that **with** executes any statements (and thus also any assignment) included in the file `<packagename>.agn`.

The function is written in the Agena language and included in the `library.agn` file.

See also: **readlib**, **run**.

```
write ([fh,] v1 [, v2 ...] [, delim ~ <str>])
```

This function prints a sequence of numbers or strings  $v_k$  to the file denoted by the handle `fh`, or to stdout (i.e. the console) if `fh` is not given. By default, no character is inserted between neighbouring values. This may be changed by passing the option `'delim':<str>` (e.g. `'delim':'|'` or `delim~'|'`) as the last argument to the function with `<str>` being a string of any length. The function is an interface to **io.write**.

```
writeline ([fh,] v1 [, v2 ...] [, delim ~ <str>])
```

This function prints a sequence of numbers or strings  $v_k$  followed by a newline to the file denoted by the handle `fh`, or to stdout (i.e. the console) if `fh` is not given. By default, no character is inserted between neighbouring values. This may be changed by passing the option `'delim':<str>` (i.e. a pair, e.g. `'delim':'|'`) as the last argument to the function with `<str>` being a string of any length. Remember that in the function call, a shortcut to `'delim':<str>` is `delim ~ <str>`. The function is an interface to **io.writeline**.

```
xpcall (f, err)
```

This function is similar to `pcall`, except that you can set a new error handler.

**xpcall** calls function `f` in protected mode, using `err` as the error handler. Any error inside `f` is not propagated; instead, **xpcall** catches the error, calls the `err` function with the original error object, and returns a status code. Its first result is the status code (a boolean), which is true if the call succeeds without errors. In this case, **xpcall** also returns all results from the call, after this first result. In case of any error, **xpcall** returns **false** plus the result from `err`.

```
zip (f, s1, s2)
```

This function zips together either two sequences or two tables by applying the function `f` to each of its respective elements. The result is a new sequence or table `s` where each element `s[k]` is determined by `s[k] := f(s1[k], s2[k])`.

`s1` and `s2` must have the same number of elements. If you pass tables, they must be table arrays, and not dictionaries.

If `s1` or `s2` have user-defined types or metatables, they are copied to the resulting structure, as well.

See also: **map**, **select**, **remove**.

## 7.2 Coroutine Manipulation

The operations related to coroutines comprise a sub-library of the basic library and come inside the table `coroutine`.

### `coroutine.create (f)`

Creates a new coroutine, with body `f`. `f` must be a Agena function. Returns this new coroutine, an object with type 'thread'.

### `coroutine.resume (co [, val1, ...])`

Starts or continues the execution of coroutine `co`. The first time you resume a coroutine, it starts running its body. The values `val1`, `...` are passed as the arguments to the body function. If the coroutine has yielded, resume restarts it; the values `val1`, `...` are passed as the results from the yield.

If the coroutine runs without any errors, resume returns **true** plus any values passed to yield (if the coroutine yields) or any values returned by the body function (if the coroutine terminates). If there is any error, resume returns **false** plus the error message.

### `coroutine.running ()`

Returns the running coroutine, or **null** when called by the main thread.

### `coroutine.status (co)`

Returns the status of coroutine `co`, as a string: 'running', if the coroutine is running (that is, it called status); 'suspended', if the coroutine is suspended in a call to yield, or if it has not started running yet; 'normal' if the coroutine is active but not running (that is, it has resumed another coroutine); and 'dead' if the coroutine has finished its body function, or if it has stopped with an error.

### `coroutine.wrap (f)`

Creates a new coroutine, with body `f`. `f` must be a Agena function. Returns a function that resumes the coroutine each time it is called. Any arguments passed to the function behave as the extra arguments to resume. Returns the same values returned by **resume**, except the first boolean. In case of error, propagates the error.

### `coroutine.yield (...)`

Suspends the execution of the calling coroutine. The coroutine cannot be running a C function, a metamethod, or an iterator. Any arguments to `yield` are passed as extra results to resume.

## 7.3 Modules

The package library provides basic facilities for loading and building modules in Agena. It exports two of its functions directly in the global environment: **require** and **module**. Everything else is exported in a table `package`.

**module** (`name` [, ...])

Creates a module. If there is a table in `package.loaded[name]`, this table is the module. Otherwise, if there is a global table `t` with the given name, this table is the module. Otherwise creates a new table `t` and sets it as the value of the global name and the value of `package.loaded[name]`. This function also initialises `t._NAME` with the given name, `t._M` with the module (`t` itself), and `t._PACKAGE` with the package name (the full module name minus last component; see below). Finally, `module` sets `t` as the new environment of the current function and the new value of `package.loaded[name]`, so that `require` returns `t`.

If `name` is a compound name (that is, one with components separated by dots), `module` creates (or reuses, if they already exist) tables for each component. For instance, if `name` is `a.b.c`, then `module` stores the module table in field `c` of field `b` of global `a`.

This function may receive optional options after the module name, where each option is a function to be applied over the module.

**require** (`modname`)

Loads the given module. The function starts by looking into the table **package.loaded** to determine whether `modname` is already loaded. If it is, then `require` returns the value stored at `package.loaded[modname]`. Otherwise, it tries to find a loader for the module.

To find a loader, first `require` queries `package.preload[modname]`. If it has a value, this value (which should be a function) is the loader. Otherwise `require` searches for a Agena loader using the path stored in `package.path`. If that also fails, it searches for a C loader using the path stored in `package.cpath`. If that also fails, it tries an all-in-one loader (see below).

When loading a C library, `require` first uses a dynamic link facility to link the application with the library. Then it tries to find a C function inside this library to be used as the loader. The name of this C function is the string `'luaopen_'` concatenated with a copy of the module name where each dot is replaced by an underscore. Moreover, if the module name has a hyphen, its prefix up to (and including) the first hyphen is removed. For instance, if the module name is `a.v1-b.c`, the function name will be `luaopen_b_c`.

If `require` finds neither an Agena library nor a C library for a module, it calls the all-in-one loader. This loader searches the C path for a library for the root name of

the given module. For instance, when requiring `a.b.c`, it will search for a C library for `a`. If found, it looks into it for an open function for the submodule; in our example, that would be `luaopen_a_b_c`. With this facility, a package can pack several C submodules into one single library, with each submodule keeping its original open function.

Once a loader is found, `require` calls the loader with a single argument, `modname`. If the loader returns any value, `require` assigns it to `package.loaded[modname]`. If the loader returns no value and has not assigned any value to `package.loaded[modname]`, then `require` assigns **true** to this entry. In any case, `require` returns the final value of `package.loaded[modname]`.

If there is any error loading or running the module, or if it cannot find any loader for the module, then `require` signals an error.

#### **package.cpath**

The path used by `require` to search for a C loader.

Agenda initialises the C path **package.cpath** in the same way it initialises the Agenda path **package.path**, using the environment variable `LUA_CPATH` (plus another default path defined in `agnconf.h`).

#### **package.loaded**

A table used by `require` to control which modules are already loaded. When you require a module `modname` and `package.loaded[modname]` is not **false**, `require` simply returns the value stored there.

#### **package.loadlib (libname, funcname)**

Dynamically links the host program with the C library `libname`. Inside this library, looks for a function `funcname` and returns this function as a C function. (So, `funcname` must follow the protocol (see `lua_CFunction`)).

This is a low-level function. It completely bypasses the package and module system. Unlike `require`, it does not perform any path searching and does not automatically add extensions. `libname` must be the complete file name of the C library, including if necessary a path and extension. `funcname` must be the exact name exported by the C library (which may depend on the C compiler and linker used).

This function is not supported by ANSI C. As such, it is only available on some platforms (Windows, Linux, Mac OS X, Solaris, BSD, plus other Unix systems that support the dlfcn standard).

### **package.path**

The path used by **require** to search for an Agena loader.

At start-up, Agena initialises this variable with the value of the environment variable `LUA_PATH` or with a default path defined in `agnconf.h`, if the environment variable is not defined. Any `';;'` in the value of the environment variable is replaced by the default path.

A path is a sequence of templates separated by semicolons. For each template, **require** will change each interrogation mark in the template by filename, which is `modname` with each dot replaced by a "directory separator" (such as `"/"` in Unix); then it will try to load the resulting file name. So, for instance, if the Agena path is

```
'./?.agn;./?.lc;/usr/local/?/init.agn'
```

the search for an Agena loader for module `foo` will try to load the files `./foo.agn`, `./foo.lc`, and `/usr/local/foo/init.agn`, in that order.

### **package.preload**

A table to store loaders for specific modules (see **require**).

### **package.seeall (module)**

Sets a metatable for `module` with its `__index` field referring to the global environment, so that this module inherits values from the global environment. To be used as an option to function `module`.

## 7.4 String Manipulation

A note in advance: All operators and **strings** package functions know how to handle many diacritics properly. Thus, the **lower** and **upper** operators know how to convert these diacritics, and various **is\*** functions recognise diacritics as alphabetic characters.

Diacritics in this context are the letters:

â	Â	ä	Ä	à	À	á	Á	å	Å	æ	Æ	ã	Ã
ê	Ê	ë	Ë	è	È	é	É	ë					
ï	Ï	î	Î	ì	Ì	í	Í	ý	Ý	ÿ			
ô	Ô	ö	Ö	ò	Ò	ø	Ø	ó	Ó	õ	Õ		
û	Û	ù	Ù	ü	Ü	ú	Ú						
ç	Ç	ñ	Ñ	đ	Đ	þ	Þ	ß					

### 7.4.1 Kernel Operators and Basic Library Functions

**replace** (s1, s2, s3)

**replace** (s1, struct)

In the first form, the operator replaces all occurrences of string *s2* in string *s1* by string *s3*.

In the second form, the operator receives a string *s1* and a table or sequence of one or more string pairs of the form *s2:s3* and replaces all occurrences of *s2* in string *s1* with the corresponding string *s3*. Thus you can replace multiple patterns with only one call to **replace**.

The return is a new string.

**s1 split s2**

Splits the string *s1* into words. The delimiter is given by string *s2*, which may consist of one or more characters. The return is a table.

**abs (s)**

With strings, returns the numeric ASCII value of the given character *s* (a string of length 1).

**s1 in s2**

This binary operator checks whether the string *s2* includes *s1* and returns its position as a number.

### **lower (s)**

Receives a string and returns a copy of this string with all uppercase letters ('A' to 'Z' plus the above mentioned diacritics) changed to lowercase ('a' to 'z' and the above mentioned diacritics). All other characters are left unchanged.

### **size (s)**

With a string s returns its length, i.e. the number of characters in s.

### **toNumber (e [, base])**

Tries to convert its argument to a number. If the argument is already a number or a string convertible to a number, then **toNumber** returns this number; otherwise, it returns **e** if **e** is a string, and **fail** otherwise. The function recognises the strings 'undefined' and 'infinity' properly, i.e. it converts them to the corresponding numeric values **undefined** and **infinity**, respectively.

An optional argument specifies the base to interpret the numeral. The base may be any integer between 2 and 36, inclusive. In bases above 10, the letter 'A' (in either upper or lower case) represents 10, 'B' represents 11, and so forth, with 'Z' representing 35. In base 10 (the default), the number may have a decimal part, as well as an optional exponent part (see 2.1). In other bases, only unsigned integers are accepted. If an option is passed, 'undefined' and 'infinity' are not converted to numbers; and if e could not be converted, **fail** is returned.

### **toString (e)**

Receives an argument of any type and converts it to a string in a reasonable format. For complete control of how numbers are converted, use **strings.format**.

If the metatable of e has a '\_\_tostring' field, then toString calls the corresponding value with e as argument, and uses the result of the call as its result.

### **trim (s)**

Returns a new string with all leading, trailing and excess embedded white spaces removed.

### **upper (s)**

Receives a string and returns a copy of this string with all lowercase letters ('a' to 'z' plus the above mentioned diacritics) changed to uppercase ('A' to 'Z' and the above mentioned diacritics). All other characters are left unchanged.

### 7.4.2 The strings Library

The **strings** library provides generic functions for string manipulation, such as finding and extracting substrings, and pattern matching. When indexing a string in Agena, the first character is at position 1 (not at 0, as in C). Indices are allowed to be negative and are interpreted as indexing backwards, from the end of the string. Thus, the last character is at position -1, and so on.

The strings library provides all its functions inside the table `strings`. It also sets a metatable for strings where the `__index` field points to the strings table. Therefore, you can use the string functions in object-oriented style. For instance, `strings.repeat(s, i)` can be written as `s:repeat(i)`.

#### **strings.diamap (s)**

The function corrects problems in the Solaris, Linux, OS/2, Windows, and DOS consoles with diacritics and ligatures read in from a text file (even .agn program files) by mapping them to their correct character codes. It takes a strings `s`, applies the mapping, and returns a new string. All other characters are returned unchanged.

Example:

```
> strings.diamap('AEIOU-í_ã+ï'):
AEIOUÄÖÜÆÅØ
```

Note that the function does not convert all existing special tokens.

#### **strings.dump (function)**

Returns a string containing a binary representation of the given function, so that a later **loadstring** on this string returns a copy of the function. `function` must be an Agena function without upvalues.

#### **strings.find (s, pattern [, init [, plain]])**

Looks for the first match of `pattern` in the string `s`. If it finds a match, then `find` returns the indices of `s` where this occurrence starts and ends; otherwise, it returns **null**. A third, optional numerical argument `init` specifies where to start the search; its default value is 1 and may be negative. A value of **true** as a fourth, optional argument `plain` turns off the pattern matching facilities, so the function does a plain "find substring" operation, with no characters in `pattern` being considered "magic". Note that if `plain` is given, then `init` must be given as well.

If the pattern has captures, then in a successful match the captured values are also returned, after the two indices.

See also: **in** operator, **strings.seek**.

**strings.format (formatstring, ...)**

Returns a formatted version of its variable number of arguments following the description given in its first argument (which must be a string). The format string follows the same rules as the `printf` family of standard C functions. The only differences are that the options/modifiers `*`, `l`, `L`, `n`, `p`, and `h` are not supported and that there is an extra option, `q`. The `q` option formats a string in a form suitable to be safely read back by the Agenda interpreter: the string is written between double quotes, and all double quotes, newlines, embedded zeros, and backslashes in the string are correctly escaped when written. For instance, the call

```
strings.format('%q', 'a string with "quotes" and \n new line')
```

will produce the string:

```
"a string with \"quotes\" and \n new line"
```

The options `c`, `d`, `E`, `e`, `f`, `g`, `G`, `i`, `o`, `u`, `X`, and `x` all expect a number as argument, whereas `q` and `s` expect a string.

This function does not accept string values containing embedded zeros.

**strings.gmatch (s, pattern)**

Returns an iterator function that, each time it is called, returns the next captures from `pattern` over string `s`.

If `pattern` specifies no captures, then the whole match is produced in each call. As an example, the following loop

```
s := 'hello world from Lua'
for w in strings.gmatch(s, '%a+') do
  print(w)
od
```

will iterate over all the words from string `s`, printing one per line. The next example collects all pairs key~value from the given string into a table:

```
create table t;
s := 'from=world, to=Lua'
for k, v in strings.gmatch(s, '(%w+)=(%w+)') do
  t[k] := v
od
```

**strings.gsub (s, pattern, repl [, n])**

Returns a copy of `s` in which all occurrences of the pattern have been replaced by a replacement string specified by `repl`, which may be a string, a table, or a function. `gsub` also returns, as its second value, the total number of substitutions made.

If `repl` is a string, then its value is used for replacement. The character `%` works as an escape character: any sequence in `repl` of the form `%n`, with `n` between 1 and 9, stands for the value of the `n`-th captured substring (see below). The sequence `%0` stands for the whole match. The sequence `%%` stands for a single `%`.

If `repl` is a table, then the table is queried for every match, using the first capture as the key; if the pattern specifies no captures, then the whole match is used as the key.

If `repl` is a function, then this function is called every time a match occurs, with all captured substrings passed as arguments, in order; if the pattern specifies no captures, then the whole match is passed as a sole argument.

If the value returned by the table query or by the function call is a string or a number, then it is used as the replacement string; otherwise, if it is **false** or **null**, then there is no replacement (that is, the original match is kept in the string).

The optional last parameter `n` limits the maximum number of substitutions to occur. For instance, when `n` is 1 only the first occurrence of pattern is replaced.

Here are some examples:

```
x := strings.gsub('hello world', '(%w+)', '%1 %1')
--> x = 'hello hello world world'

x := strings.gsub('hello world', '%w+', '%0 %0', 1)
--> x = 'hello hello world'

x := strings.gsub('hello world from Lua', '(%w+)%s*(%w+)', '%2 %1')
--> x = 'world hello Lua from'

x := strings.gsub('home = $HOME, user = $USER', '%$(%w+)', os.getenv)
--> x = 'home = /home/roberto, user = roberto'

x := strings.gsub('4+5 = $return 4+5$', '%$(.-)%$', proc (s)
return loadstring(s)()
end)
--> x = '4+5 = 9'

local t := [name~'lua', version~'5.1']
x = strings.gsub('$name%-$version.tar.gz', '%$(%w+)', t)
--> x = 'lua-5.1.tar.gz'
```

### **strings.hits (s, pattern)**

Returns the number of occurrences of substring pattern in string `s`. The function does not support regular expressions.

**strings.isAbbrev (str, pattern)**

Determines whether a string `str` is abbreviated by the substring `pattern`, i.e. whether `pattern` fits entirely to the beginning of the string `str`. The function returns **true** or **false**. The length of `pattern` must always be less than that of `str`.

If `str` or `pattern` are empty strings, the function returns **false**.

See also: **strings.isEnding**.

**strings.isAlpha (s)**

Checks whether the string `s` consists entirely of alphabetic letters and returns **true** or **false**.

See also: **strings.isLatin**.

**strings.isAlphaNumeric (s)**

Checks whether the string `s` consists entirely of numbers or alphabetic letters and returns **true** or **false**.

See also: **strings.isLatinNumeric**.

**string.isAlphaSpace (s)**

Checks whether the string `s` consists entirely of alphabetic letters and/or a white space and returns **true** or **false**.

**strings.isEnding (str, pattern)**

Determines whether a string `str` is ending in the substring `pattern`, i.e. whether `pattern` fits entirely to the end of the string `str`. The function returns **true** or **false**. The length of `pattern` must always be less than that of `str`.

If `str` or `pattern` are empty strings, the function returns **false**.

the function can be useful in linguistics if you want to check whether a word has a given inflectional ending.

See also: **strings.isAbbrev**.

**strings.isLatin (s)**

Checks whether the string `s` entirely consists of the characters 'a' to 'z', and 'A' to 'Z'. It returns **true** or **false**. If `s` is the empty string, the result is always **false**.

See also: **strings.isAlpha**.

**strings.isLatinNumeric (s)**

Checks whether the string *s* consists entirely of numbers or Latin letters and returns **true** or **false**.

See also: **strings.isAlphaNumeric** .

**strings.isLowerAlpha (s)**

Checks whether the string *s* consists entirely of the characters a to z and lower-case diacritics, and returns **true** or **false**. If *s* is the empty string, the result is always **false**.

See also: **strings.isUpperAlpha**.

**strings.isLowerLatin (s)**

Checks whether the string *s* consists entirely of the characters 'a' to 'z', and returns **true** or **false**. If *s* is the empty string, the result is always **false**.

See also: **strings.isUpperLatin** .

**strings.isMagic (s)**

Checks whether the string *s* contains one or more magic characters and returns **true** or **false**. In this function, magic characters are anything unlike the letters 'A' to 'Z', 'a' to 'z', and the diacritics listed at the top of this chapter.

**strings.isNumber(s)**

Checks whether the string *s* consists entirely of the digits 0 to 9 and returns **true** or **false**.

**strings.isNumberSpace (s)**

Checks whether the string *s* consists entirely of the digits 0 to 9 or white spaces and returns **true** or **false**.

**strings.isUpperAlpha (s)**

Checks whether the string *s* consists entirely of the capital letters 'A' to 'Z' and upper-case diacritics, and returns **true** or **false**. If *s* is the empty string, the result is always **false**.

See also: **strings.isLowerAlpha**.

**strings.isUpperLatin (s)**

Checks whether the string *s* consists entirely of the capital letters 'A' to 'Z', and returns **true** or **false**. If *s* is the empty string, the result is always **false**.

See also: **strings.isLowerLatin**.

**strings.ltrim (s [, c])**

Returns a new string with all leading white spaces removed from *s*. If a single character is passed for *c* as an optional second argument, then all leading characters given by *c* are removed.

See also: **trim** operator, **strings.rtrim**.

**strings.match (s, pattern [, init])**

Looks for the first *match of pattern* in the string *s*. If it finds one, then **match** returns the captures from the pattern; otherwise it returns **null**. If pattern specifies no captures, then the whole match is returned. A third, optional numerical argument *init* specifies where to start the search; its default value is 1 and may be negative.

**strings.put (str1, n, str2)**

Inserts a new string *str2* into the string *str1* at the given position *n*, substituting the respective character in *str1* with the new string *str2* which may consist of zero, one or more characters. The return is a new string. If *str2* is the empty string, the character in *str1* is deleted.

This function is more convenient than using a mix of substring and concatenation operators and is as fast as them.

See also: **strings.remove**.

**strings.remove (str, pos, len)**

Starting from string position *pos*, the function removes *len* characters from string *str*. The return is a new string.

It is not an error if *len* is greater than the actual length of *str*. In this case all characters starting at position *pos* are deleted.

See also: **strings.put**.

**strings.repeat (s, n)**

Returns a string that is the concatenation of *n* copies of the string *s*.

**strings.reverse (s)**

Returns a string that is the string *s* reversed.

**strings.rseek** (*s*, *pattern* [, *init*])

Starting from the right end and always running to its left beginning, the function looks for the first match of *pattern* in the string *s*. If it finds a match, then *find* returns the index of *s* where this occurrence starts with respect to its left beginning; otherwise, it returns **null**.

A third, optional numerical argument *init* specifies where to start the search; its default value is **size** *pattern* and may be negative. If *init* is positive, the search begins from the *init*'s character from the left (and also runs to the left). If *init* is negative, the search begins from the  $|init|$ 's character from the right (and runs to the left, also).

The function is useful for example in linguistic research to search for inflectional endings.

See also: **in** operator, **string.find**, **strings.seek**.

**strings.rtrim** (*s*)

Returns a new string with all trailing white spaces removed from *s*. If a single character is passed for *c* as an optional second argument, then all trailing characters given by *c* are removed.

See also: **trim** operator, **strings.ltrim**.

**strings.seek** (*s*, *pattern* [, *init*])

Looks for the first match of *pattern* in the string *s*. If it finds a match, then *find* returns the index of *s* where this occurrence starts; otherwise, it returns **null**. A third, optional numerical argument *init* specifies where to start the search; its default value is 1 and may be negative. Contrary to **strings.find**, the function does not support pattern matching facilities but is around 8 % faster. If you have to search a string from its beginning, use the faster **in** operator.

See also: **in** operator, **string.find**, **strings.rseek**.

**strings.toChars** (...)

Receives zero or more integers and returns a string with length equal to the number of arguments, in which each character has the internal numerical code equal to its corresponding argument.

Note that numerical codes are not necessarily portable across platforms.

**strings.words** (*s* [, *delim*])

Counts the number of words in a string *s*. A word is any sequence of characters surrounded by white spaces or its left and right borders. However, the user can

define any other delimiter by passing a character `delim` (of type string) as a second argument. The return is a number.

### 7.4.3 Patterns

#### Character Class:

A character class is used to represent a set of characters. The following combinations are allowed in describing a character class:

- **x**: (where x is not one of the magic characters `^$()%.[]*+-?`) represents the character x itself.
- **.**: (a dot) represents all characters.
- **%a**: represents all letters.
- **%c**: represents all control characters.
- **%d**: represents all digits.
- **%l**: represents all lowercase letters.
- **%p**: represents all punctuation characters.
- **%s**: represents all space characters.
- **%u**: represents all uppercase letters.
- **%w**: represents all alphanumeric characters.
- **%x**: represents all hexadecimal digits.
- **%z**: represents the character with representation 0.
- **%x**: (where x is any non-alphanumeric character) represents the character x. This is the standard way to escape the magic characters. Any punctuation character (even the non magic) can be preceded by a '%' when used to represent itself in a pattern.
- **[set]**: represents the class which is the union of all characters in *set*. A range of characters may be specified by separating the end characters of the range with a '-'. All classes %x described above may also be used as components in set. All other characters in set represent themselves. For example, `[%w_]` (or `[_%w]`) represents all alphanumeric characters plus the underscore, `[0-7]` represents the octal digits, and `[0-7%l%-]` represents the octal digits plus the lowercase letters plus the '-' character.
- The interaction between ranges and classes is not defined. Therefore, patterns like `[%a-z]` or `[a-%%]` have no meaning.
- **[^set]**: represents the complement of *set*, where set is interpreted as above.

For all classes represented by single letters (%a, %c, etc.), the corresponding uppercase letter represents the complement of the class. For instance, %S represents all non-space characters.

The definitions of letter, space, and other character groups depend on the current locale. In particular, the class `[a-z]` may not be equivalent to %l.

Pattern Item:

A *pattern item* may be

- a single character class, which matches any single character in the class;
- a single character class followed by '\*', which matches 0 or more repetitions of characters in the class. These repetition items will always match the longest possible sequence;
- a single character class followed by '+', which matches 1 or more repetitions of characters in the class. These repetition items will always match the longest possible sequence;
- a single character class followed by '.', which also matches 0 or more repetitions of characters in the class. Unlike '\*', these repetition items will always match the *shortest possible sequence*;
- a single character class followed by '?', which matches 0 or 1 occurrence of a character in the class;
- %n, for n between 1 and 9; such item matches a substring equal to the n-th captured string (see below);
- %bxy, where x and y are two distinct characters; such item matches strings that start with x, end with y, and where the x and y are balanced. This means that, if one reads the string from left to right, counting +1 for an x and -1 for a y, the ending y is the first y where the count reaches 0. For instance, the item %b() matches expressions with balanced parentheses.

### Pattern:

A *pattern* is a sequence of pattern items. A '^' at the beginning of a pattern anchors the match at the beginning of the subject string. A '\$' at the end of a pattern anchors the match at the end of the subject string. At other positions, '^' and '\$' have no special meaning and represent themselves.

### Captures:

A pattern may contain sub-patterns enclosed in parentheses; they describe captures. When a match succeeds, the substrings of the subject string that match captures are stored (captured) for future use. Captures are numbered according to their left parentheses. For instance, in the pattern '(a\*(.)%w(%s\*))', the part of the string matching 'a\*(.)%w(%s\*)' is stored as the first capture (and therefore has number 1); the character matching '.' is captured with number 2, and the part matching '%s\*' has number 3.

As a special case, the empty capture () captures the current string position (a number). For instance, if we apply the pattern '()aa()' on the string 'flaaap', there will be two captures: 3 and 5.

A pattern cannot contain embedded zeros. Use %z instead.

## 7.5 Table Manipulation

### 7.5.1 Kernel Operators

The following functions have been built into the kernel as unary operators.

#### **copy (table)**

The operator copies the entire contents of a table into a new table. If the table contains tables itself, those tables are also copied properly (by a `deep copying` method). Metatables and user-defined types are copied, too.

#### **filled (table)**

Checks whether table contains at least one element. The return is **true** or **false**. The function works on dictionaries, as well.

#### **join (table)**

Concatenated all string values in the table in sequential order and returns a string.

#### **map (f, table [, ...])**

Maps the function *f* on all elements of a table. See `map` in chapter 7.1 for more information.

#### **qsadd (obj)**

Raises all numeric values in table or sequence *obj* to the power of 2 and sums up these powers. The return is a number. If *obj* is empty or consists entirely of non-numbers, **null** is returned. If the table or sequence contains numbers and other objects, only the powers of the numbers are added. Entries with non-numeric keys are ignored.

#### **sadd (obj)**

Sums up all numeric values in table or sequence *obj*. The return is a number. If *obj* is empty or consists entirely of non-numbers, **null** is returned. If the object contains numbers and other objects, only the numbers are added. Entries with non-numeric keys are ignored.

#### **unique (table)**

The **unique** operator removes all holes (`missing keys`) in a table and removes multiple occurrences of the same value, if present. The return is a new table with the original table unchanged.

The following functions have been built into the kernel as binary operators.

Please note that the operators returning a Boolean work in a Cantor way, i.e.  $\{1, 1\} = \{1\} \rightarrow \text{true}$ ,  $\{1, 2\} \times \text{subset } \{1, 1, 2, 2, 3, 3\} \rightarrow \text{true}$ .

**table1 = table2**

This equality check of two tables `table1`, `table2` first tests whether `table1` and `table2` point to the same table reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `table1` and `table2` contain the same values without regard to their keys, and returns **true** or **false**. In this case, the search is quadratic.

**table1 <> table2**

This inequality check of two tables `table1`, `table2` first tests whether `table1` and `table2` do not point to the same table reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `table1` and `table2` do not contain the same values, and returns **true** or **false**. In this case, the search is quadratic.

**c in table**

Checks whether `table` contains the value `c` and returns **true** or **false**. The search is linear.

**table1 intersect table2**

Searches all values in `table1` that are also values in `table2` and returns them in a new table. The search is quadratic, so you may use **tables.bintersect** instead if you want to compare large tables since **bintersect** performs a binary search.

**table1 minus table2**

Searches all values in `table1` that are not values in `table2` and returns them as a new table. The search is quadratic, so you may use **tables.bminus** instead if you want to compare large tables since **bminus** performs a binary search.

**table1 subset table2**

Checks whether all values in `table1` are included in `table2` and returns **true** or **false**. The operator also returns **true** if `table1 = table2`. The search is quadratic.

**table1 union table2**

Concatenates two tables `table1` and `table2` simply by copying all its elements - even if they occur multiple times - to a new table.

**table1 xsubset table2**

Checks whether all values in `table1` are included in `table2` and whether `table2` contains at least one further element, so that the result is always **false** if `table1 = table2`. The search is quadratic.

## 7.5.2 tables Library

This library provides generic functions for table manipulation. It provides all its functions inside the table `tables`.

Most functions in the table library assume that the table represents an array or a list. For these functions, when we talk about the 'length' of a table we mean the result of the length operator.

**tables.bintersect (table1, table2 [, option])**

Returns all values of `table1` that are also values in `table2`. The functions performs a binary search in `table2` for each value in `table1`. If no option is given, `table2` is sorted before starting the search. If you pass an option of any value then `table2` should already have been sorted, for no correct results would be returned otherwise.

With larger tables, this function is much faster than the **intersect** operator.

The function is written in the Agena language and included in the `library.agn` file.

**tables.bisEqual (s1, s2 [, option])**

Determines whether the table or sequence `s1` contains the same values as the sequence or table `s2`. The functions performs a binary search in `s2` for each value in `s1`. If no option is given (any value), `s2` is sorted before starting the search. If you pass an option of any type then `s2` should already have been sorted, for no correct results would be returned otherwise.

With larger tables, this function is much faster than the `=` operator.

The function is written in the Agena language and included in the `library.agn` file.

**tables.bminus (table1, table2 [, option])**

Returns all values of `table1` that are not values in `table2`. The functions performs a binary search in `table2` for each value in `table1`. If no option is given, `table2` is sorted before starting the search. If you pass the option then `table2` should already have been sorted, for no correct results would be returned otherwise.

With larger tables, this function is much faster than the **minus** operator.

The function is written in the Agena language and included in the `library.agn` file.

**tables.duplicates (o, option)**

Returns all the values that are stored more than once to the given table or sequence `o`, and returns them in a table or sequence. Each duplicate is returned only once. If `option` is not given, the structure is sorted before evaluation since this is needed to determine all duplicates. The original structure is left untouched, however. If an option of any type is given, the function assumes that the structure has been already sorted.

The function is written in the Agena language and included in the `library.agn` file.

**tables.indices (tbl)**

Returns all keys of a table as a new table. See also: `tables.getvalues`.

**tables.maxn (table)**

Returns the largest positive numerical index of the given table, or zero if the table has no positive numerical indices. (To do its job this function does a linear traversal of the whole table.)

**tables.put (table, [pos,] value)**

Inserts element `value` at position `pos` in `table`, shifting up other elements to open space, if necessary. The default value for `pos` is `n+1`, where `n` is the length of the table, so that a call `tables.put(t,x)` inserts `x` at the end of table `t`.

Use the **insert element into table** statement if you want to add an element at the current end of a table.

**tables.remove (table [, pos])**

Removes from `table` the element at position `pos`, shifting down other elements to close the space, if necessary. Returns the value of the removed element. The default value for `pos` is `n`, where `n` is the length of the table, so that a call `tables.remove(t)` removes the last element of table `t`.

Use the **delete element from table** statement if you want to remove any occurrence of the table value `element` from a table.

**tables.writeTable (table, filename [, delim])**

The function is obsolete. Please use the more flexible `utils.writeCSV` function instead.

## 7.6 Set Manipulation

The following functions have been built into the kernel as unary operators.

### `copy (set)`

The operator copies the entire contents of a set into a new set. If the set contains other sets - even nested ones-, those sets are also copied properly (by a `deep copying` method). Metamethods if present, are also copied.

### `filled (set)`

Checks whether a set contains at least one element. The return is **true** or **false**.

The following functions have been built into the kernel as binary operators.

Please note that the operators returning a Boolean work in a Cantor way, i.e.  $\{1, 1\} = \{1\} \rightarrow \text{true}$ ,  $\{1, 2\} \text{ xsubset } \{1, 1, 2, 2, 3, 3\} \rightarrow \text{true}$ .

### `set1 == set2`

This equality check of two sets `set1`, `set2` first tests whether `set1` and `set2` point to the same set reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `set1` and `set2` contain the same items, and returns **true** or **false**. In this case, the search is linear.

### `table1 <=> table2`

This inequality check of two tables `set1`, `set2` first tests whether `set1` and `set2` do not point to the same set reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `set1` and `set2` do not contain the same items, and returns **true** or **false**. In this case, the search is linear.

### `c in set`

Checks whether `set` contains the item `c` and returns **true** or **false**. The search is constant.

### `set1 intersect set2`

Searches all items in `set1` that are also items in `set2` and returns them in a set. The search is linear.

**set1 minus set2**

Searches all items in `set1` that are not items in `set2` and returns them as a set. The search is linear.

**set1 subset set2**

Checks whether all items in `set1` are included in `set2` and returns **true** or **false**. The operator also returns **true** if `set1 = set2`. The search is linear.

**set1 union set2**

Concatenates two sets `set1` and `set2` simply by copying all its items to a new set.

**set1 xsubset set2**

Checks whether all items in `set1` are included in `set2` and whether `set2` contains at least one further item, so that the result is always **false** if `set1 = set2`. The search is linear.

## 7.7 Sequence Manipulation

With the exception of **map**, the following functions have been built into the kernel as unary operators.

### **copy (seq)**

The operator copies the entire contents of a sequence into a new table. If the sequence contains sequence itself, those sequence are also copied properly (by a `deep copying` method). Metatables and user-defined types are copied, too.

### **filled (seq)**

Checks whether sequence contains at least one element. The return is **true** or **false**.

### **join (seq)**

Concatenated all string values in the sequence in sequential order and returns a string.

### **qsadd (seq)**

Raises all numeric values in sequence *seq* to the power of 2 and sums up these powers. The return is a number. If *seq* is empty or consists entirely of non-numbers, **null** is returned. If the sequence contains numbers and other values, only the powers of the numbers are added.

### **sadd (seq)**

Sums up all numeric values in sequence *seq*. The return is a number. If *seq* is empty or consists entirely of non-numbers, **null** is returned. If *seq* contains numbers and other values, only the numbers are added.

### **unique (seq)**

With sequences, the **unique** operator removes multiple occurrences of the same item, if present. The return is a new sequence with the original sequence unchanged.

The following functions have been built into the kernel as binary operators.

Please note that the operators returning a Boolean work in a Cantor way, i.e. `seq(1, 1) = seq(1) → true`, `seq(1, 2) xsubset seq(1, 1, 2, 2, 3, 3) → true`.

#### **`seq1 ≡ seq2`**

This equality check of two sequences `seq1`, `seq2` first tests whether `seq1` and `seq2` point to the same sequence reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `seq1` and `seq2` contain the same values without regard to their keys, and returns **true** or **false**. In this case, the search is quadratic.

#### **`seq1 <> seq2`**

This inequality check of two sequences `seq1`, `seq2` first tests whether `seq1` and `seq2` do not point to the same sequence reference in memory. If so, it returns **true** and quits.

If not, the operator then checks whether `seq1` and `seq2` do not contain the same values, and returns **true** or **false**. In this case, the search is quadratic.

#### **`c in seq`**

Checks whether `seq` contains the value `c` and returns **true** or **false**. The search is linear.

#### **`seq1 intersect seq2`**

Searches all values in `seq1` that are also values in `seq2` and returns them in a sequence. The search is quadratic.

#### **`seq1 minus seq2`**

Searches all values in `seq1` that are not values in `seq2` and returns them as a sequence. The search is quadratic.

#### **`seq1 subset seq2`**

Checks whether all values in `seq1` are included in `seq2` and returns **true** or **false**. The operator also returns **true** if `seq1 = seq2`. The search is quadratic.

#### **`seq1 union seq2`**

Concatenates two sequences `seq1` and `seq2` simply by copying all its elements - even if they occur multiple times - to a new sequence.

**seq1 xsubset seq2**

Checks whether all values in `seq1` are included in `seq2` and whether `seq2` contains at least one further element, so that the result is always **false** if `seq1 = seq2`. The search is quadratic.

## 7.8 Mathematical Functions

### 7.8.1 Kernel Operators

The following functions have been built into the kernel as operators.

#### **abs (x)**

If  $x$  is a number, **abs** returns the absolute value of  $x$ . Complex numbers are supported.

#### **arctan (x)**

Arc tangent ( $x$  in radians). Complex numbers are supported.

#### **cos (x)**

Cosine ( $x$  in radians). Complex numbers are supported.

#### **cosh (x)**

Returns the hyperbolic cosine of  $x$ . Complex numbers are supported.

#### **entier (x)**

Rounds  $x$  downwards to the nearest integer. Complex numbers are supported.

See also: **math.ceil**.

#### **even (x)**

Checks whether  $x$  is even. Returns **true** if  $x$  is even, and **false** otherwise.

#### **exp (x)**

Exponential function, returns the value  $e^x$ . Complex numbers are supported.

#### **finite (x)**

Checks whether  $x$  is not plus or minus **infinity**, and is not **undefined** (NaN). Returns **true** if  $x$  is a 'number' and **false** otherwise.

#### **float (x)**

Checks whether the number  $x$  is a float, i.e. not an integer, and returns **true** or **false**. If  $x$  is not a number, the operator returns **fail**.

#### **gammaLn (x)**

Computes  $\ln \Gamma x$ . If  $x$  is nonpositive, the function returns **undefined**.

#### **int (x)**

Rounds  $x$  to the nearest integer towards zero.

**ln (x)**

Natural logarithm of  $x$ . If  $x$  is nonpositive, the function returns **undefined**. Complex numbers are supported.

**sign (x)**

Determines the sign of the number or complex value  $x$ . If  $x$  is a complex value, the result is determined as follows:

- 1, if  $\text{real}(x) > 0$  or  $\text{real}(x) = 0$  and  $\text{imag}(x) > 0$
- -1, if  $\text{real}(x) < 0$  or  $\text{real}(x) = 0$  and  $\text{imag}(x) < 0$
- 0 otherwise.

**sin (x)**

Sine ( $x$  in radians). Complex numbers are supported.

**sinh (x)**

Returns the hyperbolic sine of  $x$ . Complex numbers are supported.

**sqrt (x)**

Square root of  $x$ .

If  $x$  is a number and negative, the function returns **undefined**.

With complex numbers, the operator returns the complex square root, in the range of the right halfplane including the imaginary axis.

**tan (x)**

Tangent of  $x$  ( $x$  in radians). Complex numbers are supported.

**tanh (x)**

Hyperbolic tangent of  $x$  ( $x$  in radians). Complex numbers are supported.

## 7.8.2 math Library

This library is an interface to the standard C math library. It provides all its functions inside the table `math`.

**math.approx (a, b [, eps])**

Compares the two numbers  $a$  and  $b$  and checks whether they are approximately equal using a simplified relative approximation algorithm developed by Donald H. Knuth. If `eps` is omitted, `_EnvEps` is used. (The algorithm checks whether the relative error is bound to a given tolerance `eps`.)

The function returns **true** if  $a$  and  $b$  are considered equal or **false** otherwise.

**math.arccos (x)**

Returns the arc cosine of  $x$  (in radians). The function works on both numbers and complex values.

**math.arccosh (x)**

Returns the inverse hyperbolic cosine of  $x$  (in radians). The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

**math.arccoth (x)**

Returns the inverse hyperbolic cotangent of  $x$  (in radians). The function works on both numbers and complex values.

**math.arcsin (x)**

Returns the arc sine of  $x$  (in radians). The function works on both numbers and complex values.

**math.arcsinh (x)**

Returns the inverse hyperbolic sine of  $x$  (in radians). The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

**math.arctanh (x)**

Returns the inverse hyperbolic tangent of  $x$  (in radians). The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

**math.arctan2 (y, x)**

Returns the arc tangent of  $y/x$  (in radians), but uses the signs of both parameters to find the quadrant of the result. (It also handles correctly the case of  $y$  being zero.)  $x$  and  $y$  must be numbers or complex numbers.

**math.argument (z)**

Returns the argument (the phase angle) of the complex value  $z$  in radians as a number; if  $z$  is a number, the function returns 0.

### **math.binomial (n, k)**

Returns the binomial coefficient as a number. The function returns **undefined**, if  $n$  or  $k$  are negative.

### **math.convertbase (s, a, b)**

Converts a number  $s$  or a number represented as a string  $s$  from base  $a$  to base  $b$ .  $a$  and  $b$  must be integers in the range 1 to 36. The number in  $s$  must be an integer of any sign. Floats are not allowed. The return is a string. The function is implemented in the Agena language and included in the `library.agn` file.

### **math.ceil (x)**

Rounds upwards to the nearest integer larger than or equal to the number or complex number  $x$ . See the **entier** operator for a function that rounds downwards to the nearest integer. The function is implemented in the Agena language and included in the `library.agn` file.

### **math.conj (z)**

The conjugate  $x-ly$  of the complex value  $z=x+ly$ . If  $z$  is of type number, it is simply returned.

### **math.cot (x)**

Returns the cotangent  $-\tan(\pi/2+x)$  as a number. The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

### **math.coth (x)**

Returns the hyperbolic cotangent  $1/\tanh(x)$  as a number. The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

### **math.csc(x)**

Returns the cosecant  $1/\sin(x)$  as a number. The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

### **math.diff (f, x [, eps])**

Differentiates a function in one variable at the point  $x$  and returns a number. If  $eps$  is not passed, the function uses an accuracy of the value stored to `_EnvEps`. You may pass another numeric value for  $eps$  if necessary.

The function is implemented in the Agena language and included in the `library.agn` file.

**math.fact (n)**

Returns the factorial of  $n$ , i.e. the product of the values from 1 to  $n$ . If  $n$  is not an integer or if  $n$  is negative, the function returns **undefined**. The function is implemented in the Agena language and included in the `library.agn` file. It features a defaults remember table which you may extend by editing the `library.agn` file.

**math.fmod (x, y)**

Returns the remainder of the division of  $x$  by  $y$ , with  $x, y$  numbers.

**math.frac (x)**

Returns the fractional part of the number  $x$ , i.e.  $x - \text{int}(x)$ . The function is implemented in the Agena language and included in the `library.agn` file.

**math.frexp (x)**

Returns  $m$  and  $e$  such that  $x = m2^e$ ,  $e$  is an integer and the absolute value of  $m$  is in the range  $[0.5, 1)$  (or zero when  $x$  is zero).

**math.gcd (a, b)**

Returns the greatest common divisor of the numbers  $a$  and  $b$  as a number. The function is implemented in the Agena language and included in the `library.agn` file.

**math.gtrap (f, a, b [, eps])**

Integrates the function  $f$  on the interval  $[a, b]$  using a bisection method based on the trapezoid rule and returns a number. By default the function quits after an accuracy of  $\text{eps} = \text{\_EnvEps}$  has been reached. You may pass another numeric value for  $\text{eps}$  if necessary.

The function is implemented in the Agena language and included in the `library.agn` file.

**math.heaviside (x)**

The Heaviside function. Returns 0 if  $x < 0$ , **undefined** if  $x = 0$ , and 1 if  $x > 0$ . The function is implemented in the Agena language and included in the `library.agn` file.

**math.hypot (x, y)**

Returns  $\text{sqrt}(x^2 + y^2)$  with  $x, y$  numbers. This is the length of the hypotenuse of a right triangle with sides of length  $x$  and  $y$ , or the distance of the point  $(x, y)$  from the

origin. The function is slower but more precise than using **sqrt**. The return is a number.

**math.irem (x, y)**

Evaluates the remainder of an integer division  $x/y$  (with  $x, y$  two Agena numbers). The return is a number. The remainder  $r$  has the same sign as the numerator. If  $x$  and  $y$  are integers and  $q$  the integer quotient of  $x$  and  $y$ , then the function returns the remainder such that  $x = y*q + r$ ,  $|r| < |y|$  and  $x*r \geq 0$ .

**math.isPrime (x)**

Returns **true**, if the integral number  $x$  is a prime number, and **false** otherwise.

**math.lcm(a, b)**

Returns the least common multiple of two numbers  $a$  and  $b$  as a number. The function is implemented in the Agena language and included in the `library.agn` file.

**math.ldexp (m, e)**

Returns  $m2^e$  ( $e$  should be an integer).

**math.log (x, b)**

Returns the logarithm of the number or complex number  $x$  to the base  $b$ , with  $b$  a number or a complex number. The function is implemented in the Agena language and included in the `library.agn` file.

**math.log10 (x)**

Returns the base-10 logarithm of the number or complex number  $x$ . The function is implemented in the Agena language and included in the `library.agn` file.

**math.max (x, ...)**

Returns the maximum value among its arguments.

**math.min (x, ...)**

Returns the minimum value among its arguments.

**math.modf (x)**

Returns two numbers, the integral part of  $x$  and the fractional part of  $x$ .

**math.Phi**

The golden number,  $\text{Phi} = (1 + \sqrt{5})/2$ .

**math.random ([m [, n]])**

This function is an interface to the simple pseudo-random generator function `rand` provided by ANSI C. (No guarantees can be given for its statistical properties.)

When called without arguments, returns a pseudo-random real number in the range  $[0,1)$ . When called with a number `m`, `math.random` returns a pseudo-random integer in the range  $[1, m]$ . When called with two numbers `m` and `n`, `math.random` returns a pseudo-random integer in the range  $[m, n]$ .

**math.randomseed (x)**

Sets `x` as the "seed" for the pseudo-random generator: equal seeds produce equal sequences of numbers.

**math.root (x, n)**

Returns the non-principal `n`-th root of the number or complex value `x`. `n` must be an integer.

**math.roundf (x [, d])**

Rounds the number `x` to the `d`-th digit. Return is a number. If `d` is omitted, the number is rounded to the nearest integer. The following Agena code explains the algorithm used:

```
roundf := proc(x, digs) is
  local d;
  if digs = null then d := 0 else d := digs fi;
  return int((10^d)*x + sign(x)*0.5) * (10^(-d))
end;
```

**math.sec(x)**

Returns the secant  $1/\cos(x)$  as a number. The function is implemented in the Agena language and included in the `library.agn` file. The function works on both numbers and complex values.

**math.toDecimal (h [, m [, s]])**

Converts a sexagesimal time value given in hours `h`, minutes `m` and seconds `s` into its decimal representation. The optional arguments `m` and `s` default to 0. The function is implemented in the Agena language and included in the `library.agn` file.

**math.toRadians (d [, m [, s]])**

Returns the angle given in degrees *d*, minutes *m* and seconds *s*, in radians. The optional arguments *m* and *s* default to 0.

## 7.9 Input and Output Facilities

The I/O library provides two ways for file manipulation. The first one uses implicit file descriptors; that is, there are operations to set a default input file and a default output file, and all input/output operations are over these default files. The second style uses explicit file descriptors.

The table `io` provides three predefined file descriptors with their usual meanings from C: `io.stdin`, `io.stdout`, and `io.stderr`.

Unless otherwise stated, all I/O functions return **null** on failure (plus an error message as a second result) and some value different from **null** on success.

**io.close ([file])**

Closes *file*. Note that files are automatically closed when their handles are garbage collected, but that takes an unpredictable amount of time to happen. Without a *file*, closes the default output file.

**io.flush (file)**

**io.flush ()**

In the first form, saves any written data to *file*. In the second form, the function flushes default output.

**io.getkey ()**

Reads a key from the keyboard and returns its ASCII number. The function works on UNIX and Windows based platforms only. The function is not available on other platforms.

**io.input ([file])**

When called with a file name, it opens the named file (in text mode), and sets its handle as the default input file. When called with a file handle, it simply sets this file handle as the default input file. When called without parameters, it returns the current default input file.

In case of errors this function raises the error, instead of returning an error code.

**io.isfdesc (obj)**

Checks whether *obj* is a valid file handle. Returns true if *obj* is an open file handle, or **false** if *obj* is not a file handle.

```
io.lines ([filename])
```

```
io.lines ([file])
```

In the first form, the function opens the given file name in read mode and returns an iterator function that, each time it is called, returns a new line from the file.

In the second form, the function opens the given file in read mode and returns an iterator function that, each time it is called, returns a new line from the file.

Therefore, the construction

```
for keys line in io.lines(f) do body od
```

will iterate over all lines of the file denoted by `f`. When the iterator function detects the end of file, it returns **null** (to finish the loop) and automatically closes the file if a filename is given. In case of a file handle, the file is not closed.

The call `io.lines()` (without a file name) is equivalent to `io.input()@lines()`; that is, it iterates over the lines of the default input file. In this case it does not close the file when the loop ends.

```
io.open (filename [, mode])
```

This function opens a file, in the mode specified in the string `mode`. It returns a new file handle, or, in case of errors, **null** plus an error message.

The `mode` string can be any of the following:

- `'r'`: read mode (the default);
- `'w'`: write mode;
- `'a'`: append mode;
- `'r+'`: update mode, all previous data is preserved;
- `'w+'`: update mode, all previous data is erased;
- `'a+'`: append update mode, previous data is preserved, writing is only allowed at the end of file.

The `mode` string may also have a `'b'` at the end, which is needed in some systems to open the file in binary mode. This string is exactly what is used in the standard C function `fopen`.

```
io.output ([file])
```

Similar to `io.input` but operates over the default output file.

```
io.popen ([prog [, mode]])
```

Starts program `prog` in a separated process and returns a file handle that you can use to read data from this program (if mode is 'r', the default) or to write data to this program (if mode is 'w').

This function is system dependent and is not available on all platforms.

```
io.read(file)
```

```
io.read ()
```

In the first form, reads the file `file`, according to the given formats, which specify what to read. For each format, the function returns a string (or a number) with the characters read, or **null** if it cannot read data with the specified format. When called without formats, it uses a default format that reads the entire next line (see below).

The available formats are

- **'\*n'**: reads a number; this is the only format that returns a number instead of a string.
- **'\*a'**: reads the whole file, starting at the current position. On end of file, it returns the empty string.
- **'\*l'**: reads the next line (skipping the end of line), returning **null** on end of file. This is the default format.
- **number**: reads a string with up to this number of characters, returning **null** on end of file. If number is zero, it reads nothing and returns an empty string, or **null** on end of file.

In the second form, the function reads from the default input stream and returns a string or number.

```
io.readlines (filename [, options])
```

Reads the entire file with name `filename` and returns all lines in a table. If a string consisting of one or more characters is given as a further argument, then all lines beginning with this string are ignored. If the option **true** is passed, then on Windows system, diacritics in the file are properly converted to the NT console character set.

Make sure that the lines in the file have no more than 2048 characters, otherwise lines are not correctly split.

If the global system variable **\_EnvVerbose** is set to a value other than null, an error message is printed at the console if the file could not be found.

```
io.seek (file, [whence] [, offset])
```

Sets and gets the file position, measured from the beginning of the file, to the position given by `offset` plus a base specified by the string `whence`, as follows:

- **'set'**: base is position 0 (beginning of the file);
- **'cur'**: base is current position;
- **'end'**: base is end of file;

In case of success, function `seek` returns the final file position, measured in bytes from the beginning of the file. If this function fails, it returns **null**, plus a string describing the error.

The default value for `whence` is **'cur'**, and for `offset` is 0. Therefore, the call `file@seek()` returns the current file position, without changing it; the call `file@seek('set')` sets the position to the beginning of the file (and returns 0); and the call `file@seek('end')` sets the position to the end of the file, and returns its size.

```
io.setvbuf (file, mode [, size])
```

Sets the buffering mode for an output file. There are three available modes:

- **'no'**: no buffering; the result of any output operation appears immediately.
- **'full'**: full buffering; output operation is performed only when the buffer is full (or when you explicitly flush the file (see `io.flush`)).
- **'line'**: line buffering; output is buffered until a newline is output or there is any input from some special files (such as a terminal device).

For the last two cases, `size` specifies the size of the buffer, in bytes. The default is an appropriate size.

```
io.tmpfile ()
```

Returns a handle for a temporary file. This file is opened in update mode and it is automatically removed when the program ends.

```
io.write (...)
```

```
io.writeline (...)
```

Write the value of each of its arguments to standard output if the first argument is not a file handle, or to the file denoted by the first argument (a file handle). Except for the file handle, all arguments must be strings or numbers. To write other values, use `toString` or `strings.format` before `write`. `writeline` adds a new line character at the end of the data written, whereas `write` does not.

By default, no character is inserted between neighbouring values. This may be changed by passing the option `'delim':<str>` (i.e. a pair, e.g. `'delim':'|'`) as the

last argument to the function with `<str>` being a string of any length. Remember that in the function call, a shortcut to `'delim':<str>` is `delim ~ <str>`.

## 7.10 binio - Binary File Package

This package contains functions to read data from and write data to binary files.

In this chapter, `filehandle` as the file ID (or file handle) always is a positive integer greater than 2. This number is returned by the **binio.open** function and must be used in all package functions that require a file handle.

**binio.close** (`filehandle` [, `filehandle2`, ...])

Closes the files identified by the given file handle(s) and returns **true** if successful, and **fail** otherwise. **fail** will be returned if at least one file could not be closed. The function also deletes the file handles and the corresponding filenames from the **binio.openfiles** table if the file could be properly closed.

See also: **binio.open**.

**binio.filepos** (`filehandle`)

Returns the current file position relative to the beginning of the file as a number. In case of an error, **fail** is returned.

**binio.length** (`filehandle`)

The function returns the size of the file denoted by `filehandle` in bytes. In case of an error, **fail** is returned.

**binio.make** (`filename`)

Creates a file with the given `filename` (a string) in read/write mode and returns a file handle (a number) for subsequent read or write operations. Note that the file is left open. In case of errors, **fail** is returned.

The function also enters the newly opened file into the **binio.openfiles** table.

**binio.make** will be deprecated in one of the coming Agena releases, use **binio.open** instead.

**binio.open** (`filename` [, `anything`])

Opens the given file denoted by `filename` and returns a file handle (a number). If it cannot find the file, it creates it and leaves it open for further **binio** operations. The file is always opened in both read and write modes.

If an optional second argument is given (any valid Agena value), the file is opened in read mode only. Thus if the file does not yet exist, the function returns **fail**.

The function also enters the newly opened file into the **binio.openfiles** table.

See also: **binio.close**.

**binio.readchar (filehandle)**

**binio.readchar (filehandle, position)**

In the first form, the function reads a byte from the file denoted by `filename` from the current file position and increments the file position thereafter so that the next byte in the file can be read with a new call to the **binio.read** function.

In the second form, at first the file position is changed by `position` bytes (a positive or negative number or zero) relative to the current file position. After that the byte at the new file position is read. Next, the file position is being incremented thereafter so that the next byte in the file can be read with a new function call.

If the byte is successfully read, it is returned as a number. If the end of the file has been reached, **null** is returned. In case of an error, the return is **fail**.

**binio.readnumber (filehandle)**

The function reads an Agena number from the file denoted by `filename` from the current file position and returns it. If there is an error or nothing to read, **fail** is returned.

**binio.readstring (filehandle)**

The function reads a string from the file denoted by `filename` from the current file position and returns it. If there is an error or nothing to read, **fail** is returned.

**binio.rewind (filehandle)**

Sets the file position to the beginning of the file denoted by `filehandle`. The function returns the new file position as a number in case of success, and **fail** otherwise.

See also: **binio.toend**.

**binio.seek (filehandle, position)**

The function changes the file position of the file denoted by `filehandle` `position` bytes relative to the current position. `position` may be negative, zero, or positive.

The return is **true** if the file position could be changed successfully, or **fail** otherwise.

**binio.sync (filehandle)**

Flushes all unwritten content to the file denoted by the file handle. The function returns **true** if successful, and **fail** otherwise (e.g. if the file was not opened before or an error during flushing occurred).

**binio.toend (filehandle)**

Sets the file position to the end of the file denoted by `filehandle` so that data can be appended to the file without overwriting data. The function returns the file position as a number in case of success, and **fail** otherwise.

See also: **binio.rewind**.

**binio.writechar** (*filehandle*, *number*)

The function writes the given Agena *number* to the file denoted by *filehandle* at its current position. The function returns **true** in case of success and **fail** otherwise.

The *number* should be an integer with  $0 \leq \text{number} < 256$ , otherwise  $\text{number} \% 256$  will be stored to the file.

**binio.writelong** (*filehandle*, *number*)

The function writes the given Agena *number* to the file denoted by *filehandle* at its current position. The *number* should be an integer with  $\_EnvMinLong < \text{number} < \_EnvMaxLong$ , otherwise the operations is not defined.

The function returns **true** in case of success and **fail** otherwise.

**binio.writenumber** (*filehandle*, *number*)

The function writes the given Agena *number* to the file denoted by *filehandle* at its current position. The function returns **true** in case of success and **fail** otherwise. The *number* is always stored in Big Endian notation. The **binio.readnumber** function makes proper conversion to Little Endian if Agena runs on a Little Endian machine.

**binio.writestring** (*filehandle*, *string*)

The function writes the given *string* to the file denoted by *filehandle* at its current position.

The function returns **true** in case of success and **fail** otherwise. Internally, **writestring** first writes the length of the string as a C long int and then the string without a null character to the file. This information is then read by the **binio.readstring** function to efficiently return the string.

See also: **binio.readstring**.

## 7.11 Operating System Facilities

This library is implemented through table `os`.

### `os.battery ()`

On Windows 2000 and later, the function returns the current battery status of your system (usually laptops) as a table with the following information:

key	meaning
'acline'	'on', 'off', or 'unknown'
'installed'	<b>true</b> if a battery is present, and <b>false</b> otherwise
'life'	battery life in percent
'status'	either 'low' (capacity < 33%), 'medium' (capacity > 32% and < 67 %), 'high' (capacity > 66%), 'critical' (capacity < 5%), 'charging', 'no battery', 'unknown'
'charging'	<b>true</b> if battery is currently being charged, or <b>false</b> otherwise
'flag'	the battery flag, a number
'lifetime'	the remaining battery lifetime in seconds, a number (or <b>undefined</b> if it could not be determined)
'fulllifetime'	the battery lifetime in seconds when at full charge, a number (or <b>undefined</b> if it could not be determined)

On OS/2 Warp 4 and higher, the functions returns the status of the battery as a table with the following information:

key	meaning
'acline'	'on', 'off', 'unknown', or 'invalid'
'life'	battery life in percent, or 'undefined' if not available
'status'	either 'high', 'low', 'critical', 'charging', 'unknown', or 'invalid'
'flags'	OS/2 power flags
'power-management'	<b>true</b> if power management is switched on, or <b>false</b> if not.

On other operating systems, the function returns **fail**.

### `os.beep ()`

#### `os.beep (freq, dur)`

The first form applies to Windows, UNIX, and OS/2. It sounds the loudspeaker with a short `beep` and returns **null**.

The second form applies to Windows and OS /2 only. It sounds the loudspeaker with frequency `freq` (a positive integer) for `dur` seconds (a positive float). Returns **null** if a sound could be created successfully, or **fail** if nonpositive arguments were passed.

**os.computername ()**

Returns the name of the computer in Windows and UNIX. The return is a string. On other architectures, the function returns **fail**.

**os.cd (str)**

Changes into the directory given by string `str` on the file system. Returns **true** on success, and **fail**, the error message from the operating system, and the C error code otherwise.

**os.date ([format [, time]])**

Returns a string or a table containing date and time, formatted according to the given string `format`.

If the `time` argument is present, this is the time to be formatted (see the **os.time** function for a description of this value). Otherwise, `date` formats the current time.

If `format` starts with '!', then the date is formatted in Coordinated Universal Time. After this optional character, if `format` is `*t`, then `date` returns a table with the following fields: year (four digits), month (1--12), day (1--31), hour (0--23), min (0--59), sec (0--61), wday (weekday, Sunday is 1), yday (day of the year), and isdst (daylight saving flag, a boolean).

If `format` is not `*t`, then `date` returns the date as a string, formatted according to the same rules as the C function `strftime`.

When called without arguments, `date` returns a reasonable date and time representation that depends on the host system and on the current locale (that is, `os.date()` is equivalent to `os.date('%c')`).

**os.difftime (t2, t1)**

Returns the number of seconds from time `t1` to time `t2`. In POSIX, Windows, and some other systems, this value is exactly `t2-t1`.

**os.endian ()**

Determines the endianness of your system. Returns 0 for Little Endian, 1 for Big Endian, and **fail** if the endianness could not be determined.

**os.execute ([command])**

This function is equivalent to the C function `system`. It passes `command` to be executed by an operating system shell. It returns a status code, which is system-dependent. If `command` is absent, then it returns nonzero if a shell is available and zero otherwise.

**os.exit ([code])**

Calls the C function `exit`, with an optional code, to terminate the host program. The default value for `code` is the success code.

**os.fexists (filename)**

Checks whether the given file (`filename` is of type string) exists. It returns **true** or **false**.

**os.freemem ([unit])**

Returns the amount of free physical RAM available on Windows and UNIX machines.

If no argument is given, the return is in bytes. If `unit` is the string 'kbytes', the return is in kBytes; if `unit` is 'mbytes', the return is in Mbytes; if `unit` is 'gbytes', the return is in GBytes. On other architectures, the function returns **fail**.

**os.fstat (fn)**

Returns information on the file, link (UNIX only), or directory given by the string `fn` in a table of the form `[filetype, size in bytes, [last modification date in the form yyyy, mm, dd, hh, mm, ss]]`. `filetype` may be 'FILE' if `fn` is a regular file, 'LINK' if `fn` is a symbolic link, 'DIR' if `fn` is a directory, 'CHARSPECFILE' if `fn` is a character special file (a device like a terminal), 'BLOCKSPECFILE' if `fn` is a block special file (a device like a disk), or 'OTHER' otherwise.

**os.getenv (varname)**

Returns the value of the process environment variable `varname`, or **null** if the variable is not defined.

**os.isDOS ()**

Returns **true** if Agenda is run in DOS, and **false** otherwise. It also returns **false** if run from a Windows shell.

**os.isLinux ()**

Returns **true** if Agenda is run in Linux, and **false** otherwise.

**os.isOS2 ()**

Returns **true** if Agenda is run in OS/2, and **false** otherwise.

**os.isSolaris ()**

Returns **true** if Agenda is run in Solaris (including Nexenta), and **false** otherwise.

**os.isUNIX ()**

Returns **true** if Agena is run in a UNIX environment (i.e. Solaris, Linux, and Nexenta), and **false** otherwise.

**os.isWin ()**

Returns **true** if Agena is run in Windows, and **false** otherwise.

**os.login ()**

(Windows, OS/2, and UNIX only.) Returns the login name of the current user as a string. The return is a string. On other architectures, the function returns **fail**.

**os.ls (d [, options])**

Lists the contents of a directory as a table. If *d* is void, the current working directory is evaluated.

If no option is given, files, links, and directories are returned. If the optional argument 'files' is given, only files are returned. If the optional argument 'dirs' is given, only directories are returned. If the optional argument 'links' is given, only links are returned (UNIX only).

**os.lscore (d)**

Returns a table with all the files, links and directories in the given path *d*. If *d* is void, the current working directory is evaluated.

**os.md (str)**

Creates a directory given by string *str* on the file system. Returns **true** on success, and fail, the error message from the operating system, and the C error code otherwise. The function is available on OS/2, DOS, Windows, and UNIX.

**os.memstate ([unit])**

(Windows, UNIX, and OS/2 only.) Returns a table with information on current memory usage. With no arguments, the return is the respective number of bytes (integers). If *unit* is the string 'kbytes', the return is in kBytes, if *unit* is 'mbytes', the return is in MBytes.

The resulting table will contain the following values, an 'x' indicates which values are returned on your system.

Key	Description	Windows	UNIX	OS/2
'freephysical'	free physical RAM	x	x	
'totalphysical'	installed physical RAM	x	x	x
'freevirtual'	free virtual memory	x		
'totalvirtual'	total virtual memory	x		x
'resident'	occupied resident pages			x

On other architectures, the function returns **fail**.

#### **os.pwd ()**

Returns the current working directory on the file system as a string or **fail** if the path could not be determined.

#### **os.rmdir (str)**

Deletes a directory given by string *str* on the file system. Returns **true** on success, and **fail**, the error message from the operating system, and the C error code otherwise.

#### **os.rename (oldname, newname)**

Renames file or directory named *oldname* to *newname*. The function returns **true** on success. If this function fails, it returns **fail**, the error message from the operating system, and the C error code otherwise.

#### **os.remove (filename)**

Deletes the file or directory with the given name. Directories must be empty to be removed. Returns **true** on success, and **fail**, the error message from the operating system, and the C error code otherwise.

#### **os.setlocale (locale [, category])**

Sets the current locale of the program. *locale* is a string specifying a locale; *category* is an optional string describing which category to change: 'all', 'collate', 'ctype', 'monetary', 'numeric', or 'time'; the default category is 'all'. The function returns the name of the new locale, or **null** if the request cannot be honoured.

When called with **null** as the first argument, this function only returns the name of the current locale for the given category.

#### **os.system ()**

Returns information on the platform on which Agena is running.

Under Windows, it returns a table containing the string 'Windows', the major version (e.g. 'NT 4.0', '2000', etc.) as a string, the Build Number (*dwBuildNumber*) as a number, the platform ID (*dwPlatformId*) as a number, the major version

(*dwMajorVersion*), the minor version (*dwMinorVersion*), and the product type (*wProductType*) in this order.

In UNIX, OS/2, and DOS, it returns a table of strings with the name of the operating system (e.g. 'SunOS'), the release, the version, and the machine, in this order.

If the function could not determine the platform properly, it returns **fail**.

#### **os.time ([table])**

Returns the current time when called without arguments, or a time representing the date and time specified by the given table. This table must have fields *year*, *month*, and *day*, and may have fields *hour*, *min*, *sec*, and *isdst* (for a description of these fields, see the **os.date** function).

The returned value is a number, whose meaning depends on your system. In POSIX, Windows, and some other systems, this number counts the number of seconds since some given start time (the "epoch"). In other systems, the meaning is not specified, and the number returned by *time* can be used only as an argument to *date* and *difftime*.

#### **os.tmpname ()**

Returns a string with a file name that can be used for a temporary file. The file must be explicitly opened before its use and explicitly removed when no longer needed.

#### **os.wait (x)**

Waits for *x* seconds and returns **null**. *x* may be an integer or a float. This function does not strain the CPU, but execution cannot be interrupted. The function is available on OS/2, UNIX and Windows based systems only. On other architectures, the function returns **fail**.

## 7.12 The Debug Library

This library provides the functionality of the debug interface to Agena programs. You should exert care when using this library. The functions provided here should be used exclusively for debugging and similar tasks, such as profiling. Please resist the temptation to use them as a usual programming tool: they can be very slow. Moreover, several of its functions violate some assumptions about Agena code (e.g., that variables local to a function cannot be accessed from outside or that userdata metatables cannot be changed by Agena code) and therefore can compromise otherwise secure code.

All functions in this library are provided inside the `debug` table. All functions that operate over a thread have an optional first argument which is the thread to operate over. The default is always the current thread.

### **debug.debug ( )**

Enters an interactive mode with the user, running each string that the user enters. Using simple commands and other debug facilities, the user can inspect global and local variables, change their values, evaluate expressions, and so on. A line containing only the word `cont` finishes this function, so that the caller continues its execution.

Note that commands for `debug.debug` are not lexically nested within any function, and so have no direct access to local variables.

### **debug.doubleendiantest (n)**

converts a number `n` (i.e. a C double) twice and returns the converted number, the original number, and the difference between the original and the converted values, in this order.

The functions checks the internal function *DoubleToBigEndian* in the C source file `chelpers.c` used by the **binio** package on Little Endian platforms to write and read Agena numbers to/from file. If you should encounter trouble with Agena compiled with GCC on Little Endian hardware, then you might try the `-DGCC_WROUNDOFF_BUG` compilation option. The switch assumes, that on your platform, doubles consist of eight bytes.

### **debug.getfenv (o)**

Returns the environment of object `o`.

### **debug.gethook ([thread])**

Returns the current hook settings of the thread, as three values: the current hook function, the current hook mask, and the current hook count (as set by the **debug.sethook** function).

**debug.getinfo** ([thread,] function [, what])

Returns a table with information about a function. You can give the function directly, or you can give a number as the value of `function`, which means the function running at level `function` of the call stack of the given thread: level 0 is the current function (`getinfo` itself); level 1 is the function that called `getinfo`; and so on. If `function` is a number larger than the number of active functions, then `getinfo` returns **null**.

The returned table may contain all the fields returned by `lua_getinfo`, with the string `what` describing which fields to fill in. The default for `what` is to get all information available, except the table of valid lines. If present, the option 'f' adds a field named `func` with the function itself. If present, the option 'l' adds a field named `activelines` with the table of valid lines.

For instance, the expression `debug.getinfo(1,'n').name` returns a name of the current function, if a reasonable name can be found, and `debug.getinfo(print)` returns a table with all available information about the **print** function.

**debug.getlocal** ([thread,] level, local)

This function returns the name and the value of the local variable with index `local` of the function at level `level` of the stack. (The first parameter or local variable has index 1, and so on, until the last active local variable.) The function returns **null** if there is no local variable with the given index, and raises an error when called with a `level` out of range. (You can call **debug.getinfo** to check whether the level is valid.)

Variable names starting with '(' (open parentheses) represent internal variables (loop control variables, temporaries, and C function locals).

**debug.getmetatable** (object)

Returns the metatable of the given `object` or **null** if it does not have a metatable.

**debug.getregistry** ()

Returns the registry table.

**debug.getupvalue** (func, up)

This function returns the name and the value of the upvalue with index `up` of the function `func`. The function returns **null** if there is no upvalue with the given index.

**debug.setfenv** (object, table)

Sets the environment of the given `object` to the given `table`. Returns `object`.

**debug.sethook** ([thread,] hook, mask [, count])

Sets the given function as a hook. The string `mask` and the number `count` describe when the hook will be called. The string `mask` may have the following characters, with the given meaning:

- `'c'`: The hook is called every time Agenda calls a function;
- `'r'`: The hook is called every time Agenda returns from a function;
- `'l'`: The hook is called every time Agenda enters a new line of code.

With a `count` different from zero, the hook is called after every `count` instructions.

When called without arguments, **debug.sethook** turns off the hook.

When the hook is called, its first parameter is a string describing the event that has triggered its call: 'call', 'return' (or 'tail return'), 'line', and 'count'. For line events, the hook also gets the new line number as its second parameter. Inside a hook, you can call `getinfo` with level 2 to get more information about the running function (level 0 is the `getinfo` function, and level 1 is the hook function), unless the event is 'tail return'. In this case, Agenda is only simulating the return, and a call to `getinfo` will return invalid data.

**debug.setlocal** ([thread,] level, local, value)

This function assigns the value `value` to the local variable with index `local` of the function at level `level` of the stack. The function returns **null** if there is no local variable with the given index, and raises an error when called with a `level` out of range. (You can call `getinfo` to check whether the level is valid.) Otherwise, it returns the name of the local variable.

**debug.setmetatable** (object, table)

Sets the metatable for the given `object` to the given `table` (which can be **null**).

**debug.setupvalue** (func, up, value)

This function assigns the value `value` to the upvalue with index `up` of the function `func`. The function returns **null** if there is no upvalue with the given index. Otherwise, it returns the name of the upvalue.

**debug.system** (n)

Returns a table with the following system information: The size of various C types (char, int, long, float, double), the endianness of your platform, the hardware and the operating system for which the Agenda executable has been compiled.

**debug.traceback** ([thread,] [message])

Returns a string with a traceback of the call stack. An optional `message` string is appended at the beginning of the traceback. This function is typically used with **xpcall** to produce better error messages.

## 7.13 utils - Utilities

The **utils** package provides miscellaneous functions.

**utils.arraysize (strarr)**

Returns the maximum number of elements allocable to the `stringarray` userdata denoted by **strarr**.

See also: **utils.newarray**.

**utils.getarray (strarr, n)**

Returns the  $(n+1)$ -th string from the `stringarray` userdata denoted by **strarr**. Note that **n** starts from 0.

See also: **utils.newarray**.

**utils.getwholearray (strarr)**

Returns a table including all strings that are stored in the `stringarray` userdata denoted by **strarr**, with the first string at table index 1 (and not 0).

See also: **utils.newarray**.

**utils.newarray (n)**

Creates a `stringarray` userdata of exactly **n** strings,  $n > 0$ . The userdata stores (C pointers to) strings of any size, including empty strings. The strings can be set into the userdata by the **utils.setarray** function and accessed through the **utils.getarray** function.

**utils.setarray (strarr, n, str)**

Sets the string **str** into the `stringarray` userdata denoted by **strarr** at position **n**. Note that **n** starts from 0, so your first string must be stored to index 0 of the userdata.

See also: **utils.newarray**.

**utils.singlesubs (str, strarr)**

Substitutes individual characters in string **str** by corresponding replacements in the `stringarray` userdata denoted by **strarr**. The return is a new string. Note that the function tries to find a replacement for a single character in **str** by determining its integer ASCII value **n** and then accessing index **n** in the userdata. If an entry is found for index **n**, then the character is replaced, otherwise the character remains unchanged.

See also: **utils.newarray**.

Other functions in the **utils** library are:

#### **utils.calendar (x)**

Converts *x* seconds (an integer) elapsed since the beginning of an epoch to a table representing the respective calendar date in your local time. The table contains the following keys with the corresponding values:

- 'year' (integer)
- 'month' (integer)
- 'day' (integer)
- 'hour' (integer)
- 'min' (integer)
- 'sec' (integer)
- 'wday' (integer, day of the week)
- 'yday' (integer, day of the year)
- 'DST' (Boolean, is Daylight Saving Time)

If *x* is **null** or not specified, then the current system time is returned.

#### **utils.isLeapYear (x)**

Returns **true** if the given year *x* (a number) is a leap year, and **false** otherwise.

#### **utils.writeCSV (o, filename [, delim [, keyoption]])**

Creates a CSV file. The function writes all values or keys and value(s) of a table, set, or sequence *o* to a text file given by *filename*. Each (key ~) value pair is written on a separate line.

By default only values are written, the keys are ignored.

If the optional argument *delim* (a string) is given and if the value is a structure itself, then all entries in this substructure are separated by the given delimiter; default is a semicolon.

If the optional argument *keyoption* is given, then the key and the value(s) are also separated by the given delimiter (third argument) which must be passed, as well.

The function is written in the Agena language and included in the `lib/utils.agn` file.

## 7.14 stats - Statistics

This package contains procedures for statistical calculations and operates completely on tables. As a *plus* package, it is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

**stats.median (t)**

Returns the median of all numeric values in table *t* as a number.

**stats.mean (t)**

Returns the mean of all numeric values in table *t* as a number. The function is implemented in Agena and included in the `library.agn` file.

**stats.minmax (t [, 'sorted'])**

Returns a table with the minimum of all numeric values in table *t* as the first value, and the maximum as the second value. If the option 'sorted' is passed then the function assumes that all values in *t* are sorted in ascending order so that execution is much faster.

**stats.qmean (t)**

Returns the quadratic mean of all numeric values in table *t* as a number. The function is implemented in Agena and included in the `library.agn` file.

**stats.sd (t)**

Returns the standard deviation of all numeric values in table *t* as a number. The function is implemented in Agena and included in the `library.agn` file.

**stats.toVals (t)**

Converts all string values in table *t* to Agena numbers. The function is implemented in Agena and included in the `library.agn` file.

**stats.var (t)**

Returns the variance of all numeric values in *t* as a number. The function is implemented in Agena and included in the `library.agn` file.

## 7.15 calc - Calculus Package

This package contains mathematical routines to perform basic calculus. As a *plus* package, it is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

**calc.diff (f, x [, eps])**

Computes the value of the first differentiation of a function  $f$  at a point  $x$ . If  $eps$  is not passed, the function uses an accuracy of the value stored to `_EnvEps`. You may pass another numeric value for  $eps$  if necessary.

The function is implemented in Agena and included in the `lib/calc.agn` file.

**calc.fseq (f, a [, b])**

Creates a sequence **seq**( $1 \sim f(a)$ ,  $2 \sim f(a+1)$ , ...,  $(b-a+1) \sim f(b)$ ), with  $f$  a function,  $a$  and  $b$  numbers. Thus, the function  $f$  is applied to all numbers between and including  $a$  and  $b$ . The step size is 1.

**calc.fsum (f, a, b)**

Computes the sum of  $f(a)$ , ...,  $f(b)$ , with  $f$  a function,  $a$  and  $b$  numbers. If  $a > b$ , then the result is 0.

**calc.gtrap (f, a, b [, eps])**

Integrates the function  $f$  on the interval  $[a, b]$  using a bisection method based on the trapezoid rule and returns a number. By default the function quits after an accuracy of  $eps = \text{\_EnvEps}$  has been reached. You may pass another numeric value for  $eps$  if necessary.

The function is implemented in Agena and included in the `lib/calc.agn` file.

**calc.interp (tp)**

Computes a Newton interpolating polynomial as a function. The interpolation points are passed in a table  $tp$ , with each point being represented as a pair  $x_k : y_k$ .

The function is implemented in Agena and included in the `lib/calc.agn` file.

**calc.zero (f, a, b, [step [, eps]])**

Returns all roots of a function  $f$  in one variable on the interval  $[a, b]$ .

The function divides the interval  $[a, b]$  into smaller intervals  $[a, a+step]$ ,  $[a+step, a+2*step]$ , ...,  $[a+p*step, b]$ , with  $step=0.1$  if  $step$  is not given. It then looks for changes in sign in these smaller intervals and if it finds them, determines the roots using a modified regula falsi method.

The accuracy of the regula falsi method is determined by `eps`, with `eps = _EnvEps` as a default.  $f$  must be differentiable on  $[a, b]$ .

The function is implemented in Agena and included in the `lib/calc.agn` file.

## 7.16 linalg - Linear Algebra Package

This package provides basic functions for Linear Algebra. As a *plus* package, it is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

There are two constructors available to define vectors and matrices, **linalg.vector** and **linalg.matrix**. Except of these two procedures, the package functions assume that the geometric objects passed have been constructed with the above mentioned constructors.

The package includes a metatable **linalg.vmt** defined in the `lib/linalg.agn` file with metamethods for vector addition, vector subtraction, and scalar vector multiplication. Further functions are provided to compute the length of a vector with the **abs** operator and to apply unary minus to a vector.

The table **linalg.mmt** defines metamethods for matrix addition, subtraction and multiplication with a scalar. It is assigned via the `lib/linalg.agn` file, as well.

The **vector** function allows to define sparse vectors, i.e. if the component *n* of a vector *v* has not been physically set, and if *v[n]* is called, the return is 0 and not **null**.

The dimension of the vector and the dimensions of the matrix are indexed with the 'dim' key of the respective object. You should not change this setting to avoid errors. Existing vector and matrix values can be overwritten but you should take care to save the correct new values.

### **abs (A)**

Determines the length of vector *A*. This operation is done by applying the `__abs` metamethod to *A*.

### **linalg.add (A, B)**

Determines the vector sum of vector *A* and vector *B*. The return is a vector.

See also: **linalg.sub**.

### **linalg.backsubs (A, b)**

Solves the set of linear equations  $A \cdot x = b$ , where *A* is a matrix, and *b* the right-hand side vector. The return is the solution vector *x*.

### **linalg.coldim (A [, ...])**

Determines the column dimension of the matrix *A*. The return is a number.

If you pass more than one argument, then a time-consuming check whether *A* is a matrix is skipped.

**linalg.checkmatrix (A [, B, ...] [, true])**

Issues an error if at least one of its arguments is not a matrix. If the last argument is **true**, then the matrix dimensions are returned as a pair, else the function returns nothing.

Contrary to **linalg.checkvector**, the dimensions will not be checked if you pass more than one matrix.

**linalg.checksquare (A)**

Issues an error if A is not a square matrix. It returns nothing. See **linalg.issquare** for information on how this check is being done.

**linalg.checkvector (v [, w, ...])**

Issues an error if at least one of its arguments is not a vector. In case of two or more vectors it also checks their dimensions and returns an error if they are different.

If everything goes fine, the function will return the dimensions of all vectors passed.

See **linalg.isvector** for information on how the check is being done.

**linalg.coldim (A [, ...])**

Determines the column dimension of the matrix A. The return is a number.

If you pass more than one argument, then a time-consuming check whether A is a matrix, is skipped.

A more direct way of determining the column dimension is `right(A.dim)`.

See also: **linalg.rowdim**.

**linalg.column (A)**

Returns the n-th column of the matrix or row vector A as a new vector.

**linalg.crossprod (A)**

Computes the cross-product of two vectors of dimension 3. The return is a vector.

**linalg.det (A)**

Computes the determinant of the square matrix A. The return is a number.

**linalg.diagonal (v)**

Creates a square matrix A with all vector components put on the main diagonal. The first element in v is assigned A[1][1], the second element in v is assigned A[2][2], etc. Thus the result is a dim(v) x dim(v)-matrix.

**linalg.dim (A)**

Determines the dimension of a matrix or a vector A. If A is a matrix, the result is a pair with the left-hand side representing the number of rows and the right-hand side representing the number of columns. If A is a vector, the size of the vector is determined.

**linalg.dotprod (v1, v2)**

Computes the vector dot product of two vectors v1, v2 of same dimension. The vectors must consist of Agena numbers. The return is a number.

**linalg.hilbert (n [, x])**

Creates a generalized  $n \times n$  Hilbert matrix H, with  $H[i][j] := 1/(i+j-x)$ . If x is not specified, then x is 1.

**linalg.identity (n)**

Creates an identity matrix of dimension n with all components on the main diagonal set to 1 and all other components set to 0.

**linalg.inverse (A)**

Returns the inverse of the square matrix A.

**linalg.isantisymmetric (A)**

Checks whether the matrix A is an antisymmetric matrix. If so, it returns **true** and **false** otherwise.

**linalg.isdiagonal (A)**

Checks whether the matrix A is a diagonal matrix. If so, it returns **true** and **false** otherwise.

**linalg.isidentity (A)**

Checks whether the matrix A is an identity matrix. If so, it returns **true** and **false** otherwise.

**linalg.ismatrix (A)**

Returns **true** if A is a matrix, and **false** otherwise. To avoid costly checks of the passed object, the function only checks whether A is a sequence with the user-defined type 'matrix'.

**linalg.issquare (A)**

Returns **true** if A is a square matrix, i.e. a matrix with equal column and row dimensions, and **false** otherwise.

**linalg.issymmetric (A)**

Checks whether the matrix A is a symmetric matrix. If so, it returns **true** and **false** otherwise.

**linalg.isvector (A)**

Returns **true** if A is a vector, and **false** otherwise. To avoid costly checks of the passed object, the function only checks whether A is a sequence with the user-defined type 'vector'.

**linalg.LUdecomp (A, n)**

Computes the LU decomposition of the square matrix A of dimension n. The return is the resulting matrix, the permutation vector as a sequence, and a number where this number is either 1 for an even number of row interchanges done during the computation, or -1 if the number of row interchanges was odd.

**linalg.matrix (o1, o2, ..., on)**

Creates a matrix from the given structures o[k]. The structures are considered to be row vectors. Valid structures are vectors created with **linalg.vector**, tables, or sequences.

The return is a table with the user-defined type 'matrix' and a metatable **linalg.mmt** assigned to the matrix.

**linalg.mmap (f, A [, ...])**

This function maps a function f to all the components in the matrix A and returns a new matrix. The function must return only one value. See **linalg.vmap** for further information.

**linalg.mmul (A, B)**

Conducts a multiplication of a m x n- and a n x p-matrix and returns a m x p matrix.

**linalg.rowdim (A [, ...])**

Determines the row dimension of the matrix A. The return is a number.

If you pass more than one argument, then a time-consuming check whether A is a matrix, is skipped.

A more direct way of determining the column dimension is `left(A.dim)`.

See also: **linalg.coldim**.

`linalg.scalar mul (A, n)`

Performs a scalar multiplication by multiplying each element in vector A with the number n. The result is a new vector.

`linalg.sub (A , B)`

Subtracts vector B from vector A. The result is a vector.

See also: `linalg.add`.

`linalg.transpose (A)`

Computes the transpose of a  $m \times n$ -matrix A and thus returns an  $n \times m$ -matrix.

`linalg.vector (a1, a2, ...)`

`linalg.vector ([a1, a2, ...])`

`linalg.vector (seq(a1, a2, ...))`

`linalg.vector (n, [a1, a2, ...])`

`linalg.vector (n, [ ])`

Creates a vector with numeric components a1, a2, etc. The function also accepts a table or sequence of elements a1, a2, etc. (second and third form).

In the fourth form, n denotes the dimension of the vector, and  $a_k$  might be single values or key~value pairs. By a metamethod, vector components not explicitly set automatically default to 0. This allows you to create memory-efficient sparse vectors and thus matrices.

In the fifth form, a sparse zero vector of dimension n is returned.

The result is a table with the user-defined type 'vector' and a metatable assigned to allow basic vector operations with the operators `+`, `-`, `*`, unary minus and `abs`. The table key 'dim' contains the dimension of the vector created.

`linalg.vmap (f, v [, ...])`

This operator maps a function f to all the components in vector v and returns a new vector. The function f must return only one value.

If function f has only one argument, then only the function and the vector are passed to `map`. If the function has more than one argument, then all arguments *except the first* are passed right after the name of the vector.

Examples:

```
> vmap(<< x -> x^2 >>, vector(1, 2, 3) ):
[ 1, 4, 9 ]
```

```
> vmap(<< (x, y) -> x > y >>, vector(1, 0, 1), 0): # 0 for y
[ true, false, true ]
```

See also: **linalg.vzip**.

**linalg.vzip (f, v1, v2)**

This function zips together two vectors by applying the function  $f$  to each of its respective components. The result is a new vector  $v'$  where each element  $v'[k]$  is determined by  $s[k] := f(v1[k], v2[k])$ .

$v1$  and  $v2$  must have the same dimension.

See also: **linalg.vmap**.

**linalg.zero (n)**

Creates a zero vector of length  $n$  with all its components physically set to 0. If you want to create a sparse zero vector of dimension  $n$ , enter: `linalg.vector(n, [])`.

## 7.17 clock - Clock Package

This package contains mathematical routines to perform basic operations on time values, i.e. hours, minutes, and seconds.

As a *plus* package, it is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

A time value is always defined using the **clock.time** constructor. You may apply the ordinary +, -, and \* operators in order to add, subtract or multiply values.

All functions are implemented in Agena and included in the `lib/clock.agn` file.

**clock.add** (*s1*, *s2* [, ...])

The function adds two or more values of type time. The return is a value of type time.

**clock.adjust** (*s*)

The function adjusts the representation of time values in a time object *s* by applying the rules described in the description of **clock.time**.

**clock.mul** (*x1*, *x2*)

multiplies the numeric value *x1* with the time value *x2* (of type time). **mul** converts *x2* to seconds, and then multiplies *x2* with *x1*. The arguments may be in reverse order.

The return is a value of type time.

**clock.sub** (*s1*, *s2* [, ...])

The function subtracts two or more values of type time. The return is a value of type time.

**clock.time** (*min*)

**clock.time** (*min*, *sec*)

**clock.time** (*hrs*, *min*, *sec*)

This function is used to define time values, where *hrs*, *min*, *sec* are numbers.

In the first form, minutes are defined. The return is a value of type time of the form `time(0, min, 0)`.

In the second form, both minutes and seconds are defined. The return is a value of type time of the form `time(0, min, sec)`.

In the third form, both hours, minutes, and seconds are defined and returned as a value of type time of the form `time(hrs, min, sec)`. (*hrs* may be set to 0.)

By default, if `min > 59` and / or if `sec > 59`, proper adjustments are made before the time value is returned. If `min > 59` the call to **time** returns `time(hrs + 1, min - 60, sec)`. If `sec > 59` the call to `time` returns `time(hrs, min + 1, sec - 60)`. The default is set by the global variable `_clockAdjust` which is assigned **true** at initialisation of the package if it has not already been set **false** before the clock package has been loaded.

If `_clockAdjust` is set false then no adjustments are made to the arguments. You can use **clock.adjust** to apply the adjustments described above.

## 7.18 bits - Bitwise Operators Package

This package contains four operators to conduct bitwise manipulations of integers.

As a *plus* package, it is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

All functions are implemented in Agena and included in the `lib/bits.agn` file.

**bits.band (a, b)**

Returns the bitwise **and** of the two integers *a*, *b*, i.e. each bit in the result is set if and only if each of the corresponding bits in the converted operands is set.

**bits.bnot (a)**

Inverts all bits in the integer *a* and returns the converted number.

**bits.bor (a, b)**

Returns the bitwise inclusive **or** of the two integers *a*, *b*, i.e. each bit in the result is set if and only if at least one of the corresponding bits in the converted integers is set.

**bits.xor (a, b)**

Returns the bitwise exclusive **or** of the operands the two integers *a*, *b*, i.e. each bit in the result is set if and only if exactly one of the corresponding bits in the converted integers is set.

## Chapter Eight

# Agenda Database System

## 8 Agena Database System

As a *plus* package, this simple database is not part of the standard distribution and must be activated with the **readlib** or **with** functions.

Agena is a database for storing and accessing strings and currently supports three `base` types:

1. Sorted `databases` with a key and one or more values,
2. sorted `lists` which store keys only,
3. unsorted `sequences` to hold any value (but no keys).

With databases and lists, each record is indexed, so that access to it is very fast. If you store data with the same key multiple times in a database, the index points to the last record stored, so you always get a valid record.

Sequences do not have indexes, so searching in sequences is rather slow. However, all values can be read into the Agena environment very fast and stored to a set (using `ads.getall`).

The Agena Database System (ADS) pays attention to both file size and fast I/O operation. To reduce file size, the keys (and values) are stored with their actual lengths (of C type long integer, so keys and values can be of almost unlimited size) and they are not extended to a fixed standard length. To fasten I/O operations, the length of each key (and value) is also stored within the base file.

Section	Description
header	various information on the data file, including the maximum number of possible records, the actual number of records, and the type of the base (database, list, or sequence).
index	only with databases and lists: area containing all file positions of the actual records. The index section is always sorted. Sequences do not contain an index section.
records	key-value pairs with databases, and keys with lists or sequences.

Note that by setting the global system variable `_EnvVerbose` to **null**, some non-critical warning messages are suppressed.

A sample session:

First activate the package:

```
> with 'ads';
```

Create a new database (file `c:\test.agb`) including all administration data like number of records, etc.:

```
> createbase('c:/test.agb');
```

Open the database for processing. The variable `fh` is the file handle which references to the database file (`c:\test.agb`) and is used in all ads functions.

```
> fh := openbase('c:/test.agb');
```

Put an entry into the database with key ``Duck`` and value ``Donald``.

```
> writebase(fh, 'Duck', 'Donald');
```

Check what is stored for ``Duck``.

```
> readbase(fh, 'Duck'):
Donald
```

Show information on the database:

```
> attrib(fh):
keylength ~ 31           # Maximum length for key
type ~ 0                 # database type, 0 for relational database
stamp ~ AGENA DATA SYSTEM # name of database
indexstart ~ 256         # begin of index section in file
commentpos ~ 0           # position of a description, 0 because none
                          # was given.
version ~ 300            # base version, here 3.00
maxsize ~ 20000          # maximum number of possible records. Agena
                          # automatically extends the database, if
                          # this number is exceeded.
indexend ~ 80255         # end of index section
creation ~ 2008/01/18-19:00:50 # number of creation
columns ~ 2              # number of columns
size ~ 1                 # number of actual entries
```

Close the database. After that you cannot read or enter any entries. Use the **open** function if you want to have access again.

```
> closebase(fh);
```

On all types, you may use the following procedures:

#### **ads.attrib (filehandle)**

Returns a table with all attributes of the ``base`` file. The table includes the following keys:

Key	Description	Type
'columns'	The number of columns in the base.	number
'commentpos'	The position of a comment in the base. If no comment is present, its value is 0.	number

Key	Description	Type
'creation'	The date of creation of the base. The return is a formatted string including date and time.	string
'indexstart'	the first byte in the base file of the index section.	number
'indexend'	the last byte in the base file of the index section.	number
'keysize'	the maximum length of the record key.	number
'maxsize'	total number of data sets allowed.	number
'size'	the actual number of valid data sets (see <code>ads.size</code> as a shortcut).	number
'stamp'	The base stamp at the beginning of the file.	string
'type'	Indicator for database (0), list (1), or sequence (2).	number
'version'	The base version.	number

If the file is not open, **attrib** returns **false**.

See also: **ads.free**, **ads.size**.

#### **ads.clean (filehandle)**

Physically deletes all entries that have become invalid (i.e. replaced by new values) from the database or list. The file index section is adjusted accordingly and the file shrunk to the new reduced size.

If there are no invalid records, **false** is returned. If all records could be deleted successfully, **true** is returned. If the file is not open, the result is **fail**. If a file truncation error occurred, `clean` quits with an error. The function issues an error if the file contains a sequence.

#### **ads.closebase (filehandle [, filehandle2, ...])**

Closes the base(s) identified by the given file handle(s) and returns **true** if successful, and **false** otherwise. **false** will be returned if at least one base could not be closed. The function also deletes the file handles and the corresponding filenames from the `ads.openfiles` table.

```
ads.comment (filehandle)
ads.comment (filehandle, comment)
ads.comment (filehandle, '')
```

In the first form, the function returns the comment stored to the database or list if present. The return is a string or **null** if there is no comment.

In the second form, `ads.comment` writes or updates the given comment to the database or list and if successful, returns **true**. The comment is always written to the

end of the file. If it could not successfully add or update a comment, the function quits with an error.

In the third form, by passing an empty string, the existing comment is entirely deleted from the database or list.

If `filehandle` points to a sequence, **an error is** issued, and no comment is written. **fail** is returned, if the file is not open.

Internally, the position of the comment is stored in the file header. See `ads.attrib['commentpos']`.

```
ads.createbase (filename
    [, number_of_records [, type [, number_of_columns
    [, length_of_key [, description]]]])
```

Creates and initialises the index section of the new base with the given number of columns. It returns the file handle as a number, and closes the created file.

Arguments / Options:

filename	The path and full name of the base file.
number_of_records	The maximum number of records in the base. Default is 20000. If you pass 0, fail is returned and the base is not created.
type	By default, the type is 'database'. If you pass the string 'list', then a list is created. The string 'seq' creates a sequence. If the type passed is not known, <b>fail</b> is returned and no base is created.
number_of_columns	The number of columns in a database. Default: 2 (key and value). If the base is not a database, this option is ignored. If the number of columns is nonpositive, <b>fail</b> is returned and no base is created.
length_of_key	The maximum length of the base key. Note that internally, the length is incremented by 1 for the terminating \0 character. Default: 31 including the terminating \0 character.
description	A string with a description of the contents of the base. A maximum of 75 characters are allowed (including the \0 character). If the string is too long, it is truncated. Default: 75 spaces.

```
ads.createseq (filename)
```

Creates a sequence with the given `filename` (a string). The function is written in the Agena language and can be used after running readlib 'ads'.

```
ads.desc (filehandle)  
ads.desc (filehandle, description)
```

In the first form, returns the description of a base stored in the file header.

In the second form, **ads.desc** sets or overwrites the description section of a database or list. Pass the description as a string. If the string is longer than 75 characters, **fail** is returned and there are no changes to the base file. If the file is not open, **fail** is returned, as well. If it was successful, the return is **true**.

```
ads.expand (filehandle [, n])
```

Increases the maximum number of datasets by n records (n an integer). By default, n is 10. Internally, all data sets are shifted, so that the index section in the data file can be extended - so the greater n, the faster shifting will be, which is significant for large files.

The function returns **fail** if the file is not open, and **true** otherwise. It issues an error if the file contains a sequence.

```
ads.free (filehandle)
```

Determines the number of free data sets and returns them as an integer. If the base has not open, it returns **fail**. See also: **ads.attrib**.

```
ads.getall (filehandle)
```

Converts a sequence to a set and returns this set. The function automatically initialises the set with the number of entries in the sequence. If the file is not open, **fail** is returned.

See also: **ads.getkeys**, **ads.getvalues**.

```
ads.getkeys (filehandle)
```

Gets all valid keys in a database or list and returns them in a table. Argument: file handle (integer). If the file is not open, **fail** is returned. If the base is empty, **null** is returned. The function issues an error if the file contains a sequence.

See also: **ads.get**, **ads.getvalues**.

```
ads.getvalues (filehandle [, column])
```

By default gets all valid entries in the second column in a database and returns them in a table. If the optional argument column is given, the entries in this column are returned. Argument: file handle (integer). If the file is not open or if the column does not exist, **fail** is returned. If the base is empty, **null** is returned. With lists, the return is always **null**.

See also: `ads.get`, `ads.getkeys`.

**`ads.index (filehandle, key)`**

Searches for the given key (a string) in the base pointed to by `filehandle` and returns its file position as a number. If there are no entries in the set, the function returns **null**. If the file is not open, **fail** is returned.

**`ads.indices (filehandle)`**

Returns the file positions of all valid detests as a table.

If the file is not open, `indices` returns **fail**. If there are no entries in the base, the return is an empty table, otherwise a table with the indices is returned. The function issues an error if the file contains a sequence.

See also `ads.retrieve`, `ads.invalids`, `ads.peek`, `ads.index`.

**`ads.invalids (filehandle)`**

Returns the file positions of all invalid records in a database as a table.

If the file is not open, `invalids` returns **fail**. If no invalid entries are found, the return is an empty table. See also `ads.retrieve`. Note that the function also works with lists. However, since lists never contain invalid records, an empty table will always be returned with lists.

With sequences, the function issues an error.

**`ads.iterate (filehandle)`**

Iterates sequentially and in ascending order over all keys in the database or list. With databases, both the next key and its corresponding value are returned. With lists, only the next key is returned.

The very first key can be accessed with an empty string. If there are no more keys left, the function returns **null**. If the database is empty, **null** is returned as well. If the file is not open, the function returns **fail**.

Example:

```
> s, t := ads.iterate(fh, '');  
> s, t := ads.iterate(fh, s);
```

**ads.openbase (filename [, anything])**

Opens the base with name filename and returns a file handle (a number). If it cannot find the file, or the base has not the correct version number, the function returns **fail**. The base is opened in both read and write mode.

If an optional second argument is given (any valid Agenda value), the base is opened in read mode only.

The function also enters the newly opened file into the ads.openfiles table.

**ads.openfiles**

A global table containing all files currently open. Its keys are the file handles (integers), the values the file names (strings). If there are no open files, ads.openfiles is an empty table.

**ads.peek (filehandle, position)**

Returns both the length of an entry (including the terminating \0 character) and the entry itself at the given file position as two values (an integer and a string). The function is save, so if you try to access an invalid file position, the function will exit returning **fail**. It issues an error if the file contains a sequence.

See also ads.index, ads.retrieve.

**ads.rawsearch (filehandle, key [, column])**

With databases, the function searches all entries in the given column for the substring key and returns all respective keys and the matching entries in a table. If column is omitted, the second column is searched. The value for column must be greater than 0, so you can also search for keys.

With lists and sequences, the function always returns **null**. If the base is empty, **null** is returned.

If the file is not open or the column does not exist, the function returns **fail**.

See also ads.read, ads.getvalues.

**ads.readbase (filehandle, key)**

With databases, the function returns the entry (a string) to the given key (also a string). With lists and sequences, the function returns **true** if it finds the key, and **false** otherwise.

If the file is not open, `read` returns **fail**. If the base is empty, **null** is returned. The function uses binary search.

See also `ads.rawsearch`.

#### **ads.remove (filehandle, key)**

With databases, the function deletes a key-value pair from the database; with lists, the key is deleted. Physically, only the key to the record is deleted, the key or key-value pair still resides in the record section but cannot be found any longer.

The function returns **true** if it could delete the data set, and **false** if the set to be deleted was not found. If the file is not open, `delete` returns fail. The function issues an error if the file contains a sequence.

If you want to physically delete all invalid records, use **ads.clean**.

#### **ads.retrieve (filehandle, position)**

Gets a key and its value from a database or list (indicated by its first argument, the file handle) at the given file position (an integer, the second argument). Two values are returned: the respective key and its value. With lists, only the key is returned.

The function is safe, so if you try to access an invalid file position, the function will exit and return **fail**.

If the file is not open, `retrieve` returns **fail**. The function issues an error if the file contains a sequence.

See also `ads.indices`, `ads.invalids`.

#### **ads.sizeof (filehandle)**

Returns the number of valid records (an integer) in the base pointed to by filehandle. If the base pointed to by the numeric filehandle is not open, the function returns **fail**.

#### **ads.sync (filehandle)**

Flushes all unwritten content to the base file. The function returns **true** if successful, and **fail** otherwise (e.g. if the file was not opened before or an error during flushing occurred).

```
ads.writebase (filehandle, key [, value1, value2, ...])
```

With databases, the function writes the key (a string) and the values (strings) to the database file pointed to by filehandle (an integer). If value is omitted, an empty string is written as the value.

With lists, the function writes only the key (a string) to the database file. If you pass values, they are ignored. If the key already exists, nothing is written or done and **true** is returned. Thus, lists never contain invalid records.

In both cases, the index section is updated. If a key already exists, its position in the index section is deleted and the new index position is inserted instead (in this case there is no reshifting). This does not remove the actual key-value pair in the record section. The function always writes the new key-value pair to the end of the file. (The file position after the write operation has completed is always 0.)

If the maximum number of possible records is exceeded, the base is automatically expanded by 10 records. You do not need to do this manually.

write returns the **true** if successful. If the file is not open, write returns **fail**.

## Chapter Nine

# C API Functions

## 9 C API Functions

As already noted in Chapter 1, Agena features almost the same C API as Lua 5.1 so you are able to easily integrate your C packages and functions written for Lua 5.1 in Agena.

The following C API functions have been changed to remove automatic string-to-number conversion:

API function	Lua source file
lua_isnumber	lapi.c
lua_isstring	lapi.c
luaL_checknumber	lauxlib.c
luaL_checkinteger	lauxlib.c

Table 14: Modified Lua C API functions

Except for the above mentioned functions, no other modifications have been made to C API functions that are part of Lua 5.1.

For a description of the API functions taken from Lua, see its Lua 5.1 manual.

Agena features a macro **agn\_Complex** which is a shortcut for complex double.

The following API functions have been added (see files `lapi.c` and `lua.h`):

### **agn\_ccall**

```
agn_Complex agn_ccall (lua_State *L, int nargs, int nresults);
```

Exactly like `lua_call`, but returns a complex value as its result, so a subsequent conversion to a complex number via stack operation is avoided. If the result of the function call is not a complex value, 0 is returned. **agn\_ccall** pops the function and its arguments from the stack.

### **agn\_checkcomplex**

```
LUALIB_API agn_Complex agn_checkcomplex (lua_State *L, int idx)
```

Checks whether the value at index `idx` is a complex value and returns it. An error is raised if the value at `idx` is not of type complex.

### **agn\_checklstring**

```
const char *agn_checklstring (lua_State *L, int idx, size_t *len);
```

Works exactly like `luaL_checklstring` but does not perform a conversion of numbers to strings.

### **agn\_checknumber**

```
lua_Number agn_checknumber (lua_State *L, int idx);
```

Checks whether the value at index `idx` is a number and returns this number. An error is raised if the value at `idx` is not a number. This procedure is an alternative to `luaL_checknumber` for it is around 14 % faster in execution while providing the same functionality by avoiding different calls to internal Auxiliary Library functions.

### **agn\_checkstring**

```
const char *agn_checkstring (lua_State *L, int idx);
```

Works exactly like `luaL_checkstring` but does not perform a conversion of numbers to strings. An error is raised if `idx` is not a string.

### **agn\_complexgetimag**

```
LUA_API void agn_complexgetimag (lua_State *L, int idx)
```

Pushes the imaginary part of the complex value at position `idx` onto the stack.

### **agn\_complexgetreal**

```
LUA_API void agn_complexgetreal (lua_State *L, int idx)
```

Pushes the real part of the complex value at position `idx` onto the stack.

### **agn\_copy**

```
LUA_API void agn_copy (lua_State *L, int idx)
```

Returns a true copy of the structure at stack index `idx`. The copy is put on top of the stack, but the original structure is not removed.

## **agn\_createcomplex**

```
LUA_API void agn_createcomplex (lua_State *L, agn_Complex c)
```

Pushes a value of type complex onto the stack with its complex value given by `c`.

## **agn\_createpair**

```
void agn_createpair (lua_State *L, int idxleft, int idxright);
```

Pushes a pair onto the stack with the left operand determined by the value at index `idxleft`, and the right operand by the value at index `idxright`. The left and right values are *not* popped from the stack.

## **agn\_creatertable**

```
LUA_API void agn_creatertable (lua_State *L, int idx)
```

Creates an empty remember table for the function at stack index `idx`. It does not change the stack.

## **agn\_createseq**

```
void agn_createseq (lua_State *L, int nrec);
```

Pushes a sequence onto the top of the stack with `nrec` preallocated places (`nrec` may be zero).

## **agn\_createset**

```
void agn_createset (lua_State *L, int nrec);
```

Pushes an empty set onto the top of the stack. The new set has space pre-allocated for `nrec` items.

## **agn\_deletertable**

```
LUA_API void agn_deletertable (lua_State *L, int objindex)
```

Deletes the remember table of the procedure at stack index `idx`. If the procedure has no remember table, nothing happens. The function leaves the stack unchanged.

## agn\_fnext

```
int agn_fnext (lua_State *L, int indextable, indexfunction);
```

Pops a key from the stack, and pushes four values in the following order: the key of a table given by `indextable`, its corresponding value, the function at stack number `indexfunction`, and the value from the table at the given `indextable`. If there are no more elements in the table, then **agn\_fnext** returns 0 (and pushes nothing).

The function is useful to avoid duplicating values on the stack for **lua\_call** and the iterator to work correctly.

A typical traversal looks like this:

```
/* table is in the stack at index 't', function is at stack index 'f' */
lua_pushnil(L); /* first key */
while (lua_fnext(L, t, f) != 0) {
    /* 'key' is at index -4, 'value' at -3, function at -2, and 'value'
       at -1 */
    lua_call(L, 1, 1); /* call the function with one arg & one result */
    lua_pop(L, 1);     /* removes result of lua_call;
                       keeps 'key' for next iteration */
}
```

While traversing a table, do not call **lua\_tolstring** directly on a key, unless you know that the key is actually a string. Recall that **lua\_tolstring** changes the value at the given index; this confuses the next call to **lua\_next**.

## agn\_getfunctiontype

```
LUA_API int agn_getfunctiontype (lua_State *L, int idx)
```

Returns 1 if the function at stack index `idx` is a C function, 0 if the function at `idx` is an Agena function, and -1 if the value at `idx` is no function at all.

## agn\_gettrtable

```
LUA_API int agn_gettrtable (lua_State *L, int idx)
```

Pushes the remember table if the function at stack index `idx` onto the stack and returns 1. If the function does not have a remember table, it pushes nothing and returns 0.

## agn\_gettrtablewritemode

```
int agn_gettrtablewritemode (lua_State *L, int idx)
```

**Returns** 0 if the remember table of the function at stack index `idx` cannot be updated by the **return** statement (i.e. if it is an rotatable), 1 if it can (i.e. if it is an

rtable), 2 if the function at `idx` has no remember table at all, and -1 if the value at `idx` is not a function.

### **agn\_getseqstring**

```
const char *agn_getseqstring (lua_State *L, int idx, int n, size_t *l);
```

Gets the string at index `n` in the sequence at stack index `idx`. The length of the string is stored to `l`.

### **agn\_getinumber**

```
lua_Number agn_getinumber (lua_State *L, int idx, int n);
```

Returns the value `t[n]` as a *lua\_Number*, where `t` is a table at the given valid index `idx`. If `t[n]` is not a number, the return is 0. The access is raw; that is, it does not invoke metamethods.

### **agn\_gettstring**

```
const char *agn_gettstring (lua_State *L, int idx, int n);
```

Returns the value `t[n]` as a *const char*, where `t` is a table at the given valid index `idx`. If `t[n]` is not a string, the return is **null**. The access is raw; that is, it does not invoke metamethods.

### **agn\_getutype**

```
int agn_getutype (lua_State *L, int idx);
```

Returns the user-defined type of a procedure, sequence, set, or pair at stack position `idx` as a string and pushes it onto the top of the stack. If no user-defined type has been defined, the function returns 0 and pushes nothing onto the stack.

See also: **agn\_setutype**.

### **agn\_isfail**

```
int agn_isfail (lua_State *L, int idx);
```

Returns 1 if the Boolean value at the given acceptable index results to fail, 0 otherwise (**true** and **false**).

### **agn\_isfalse**

```
int agn_isfalse (lua_State *L, int idx);
```

Returns 1 if the Boolean value at the given acceptable index results to **false**, 0 otherwise (**true** and **fail**).

### **agn\_isutype**

```
int *agn_isutype (lua_State *L, int idx, const char *str);
```

Checks whether the type at stack index `idx` is the user-defined type denoted by `str`. It returns 1 if the given user-defined type has been found, and 0 otherwise.

### **agn\_isutypeset**

```
int *agn_isutypeset (lua_State *L, int idx, const char *str);
```

Checks whether a user-defined type has been set for the given object at stack position `idx`. It returns 1 if a user-defined type has been set, and 0 otherwise. The function accepts any Agena types. By default, if the object is not a sequence, a pair, set, or procedure, it returns 0.

### **agn\_issequitype**

```
int *agn_issequitype (lua_State *L, int idx, const char *str);
```

Checks whether the type at stack index `idx` is a sequence and whether the sequence has the user-defined type denoted by `str`. It returns 1 if the above condition is true, and 0 otherwise.

### **agn\_issetutype**

```
int *agn_issetutype (lua_State *L, int idx, const char *str);
```

Checks whether the type at stack index `idx` is a set and whether this set has the user-defined type denoted by `str`. It returns 1 if the above condition is true, and 0 otherwise.

## agn\_istableutype

```
int *agn_istableutype (lua_State *L, int idx, const char *str);
```

Checks whether the type at stack index `idx` is a table and whether the table has the user-defined type denoted by `str`. It returns 1 if the above condition is true, and 0 otherwise.

## agn\_istrue

```
int agn_istrue (lua_State *L, int idx);
```

Returns 1 if the Boolean value at the given acceptable index results to **true**, 0 otherwise (**false** and **fail**).

## agn\_isverbose

```
LUA_API int agn_isverbose (lua_State *L);
```

Checks whether the global system variable `_EnvVerbose` is set to anything but **null** or **false**. If `_EnvVerbose` is set, the function returns 1, otherwise (`_EnvVerbose` is unassigned or **false**) it returns 0.

## agn\_ncall

```
lua_Number agn_ncall (lua_State *L, int nargs, int nresults);
```

Exactly like `lua_call`, but returns a numeric result as an Agena number, so a subsequent conversion to a number via stack operations is avoided. If the result of the function call is not numeric, 0 is returned. **agn\_ncall** pops the function and its arguments from the stack.

## agn\_nops

```
size_t agn_nops (lua_State *L, int idx);
```

Determines the number of actual table, set, or sequence entries at `t[idx]`. If the value at `idx` is not a table, set, or sequence, it returns 0. With tables, this procedure is an alternative to **lua\_objlen** if you want to get the size of a table since **lua\_objlen** does not return correct results if there are holes in the table or if the table is a dictionary.

### **agn\_optcomplex**

```
agn_Complex agn_optcomplex (lua_State *L, int narg, agn_Complex z);
```

If the value at index `narg` is a complex number, it returns this number. If this argument is absent or is **null**, the function returns complex `z`. Otherwise, raises an error.

### **agn\_pairgeti**

```
void agn_pairgeti (lua_State *L, int idx, int n);
```

Returns the left operand of a pair at stack index `idx` if `n` is 1, and the right operand if `n` is 2, and puts it onto the top of the stack. You have to make sure that `n` is either 1 or 2.

### **agn\_pairrawget**

```
void agn_pairrawget (lua_State *L, int index);
```

Pushes onto the stack the left or the right hand value of a pair `t`, where `t` is the value at the given valid index `index` and the number `k` (`k=1` for the left hand side, `k=2` for the right hand side) is the value at the top of the stack. It does not invoke any metamethods. This function pops both `k` from the stack. It does not invoke any metamethods.

### **agn\_pairrawset**

```
void agn_pairrawset (lua_State *L, int index);
```

Does the equivalent to `p[k] := v`, where `s` is a pair at the given valid index `index`, `v` is the value at the top of the stack, and `k` is the value just below the top.

This function pops both the key and the value from the stack. It does not invoke any metamethods.

### **agn\_poptop**

```
void agn_poptop (lua_State *L);
```

Pops the top element from the stack. The function is more efficient than `lua_pop(L, 1)`.

## agn\_poptoptwo

```
void agn_poptoptwo (lua_State *L);
```

Pops the top element and the value just below the top from the stack. The function is more efficient than `lua_pop(L, 2)`.

## agn\_seqsize

```
int agn_seqsize (lua_State *L, int idx);
```

Returns the number of items currently stored to the sequence at stack index `idx`.

## agn\_seqstate

```
void agn_seqstate (lua_State *L, int idx, size_t a[])
```

Returns the actual number of items and the maximum number of items assignable to the sequence at index `idx` in `a`, a C array with two entries. The actual number of items is stored to `a[0]`, the maximum number of entries to `a[1]`. If `a[1]` is 0, then the number of possible entries is infinite.

## agn\_setrttable

```
LUA_API void agn_setrttable (lua_State *L, int find, int kind, int vind)
```

Sets argument~return values to the function at stack index `find`. The argument list reside at a table array at stack index `kind`, the return list are in another table at stack index `vind`. See the description for the **rset** function for more information.

## agn\_setutype

```
void agn_setutype (lua_State *L, int idxobj, int idxtype);
```

Sets a user-defined type of a procedure, sequence, set, or pair. The object is at stack index `idxobj`, the type (a string) is at position `idxtype`. The function leaves the stack unchanged.

If **null** is at `idxtype`, the function deletes the user-defined type.

Setting the type of a sequence or pair also causes the pretty printer to display the string passed to the function instead of the usual output at the console. This does not apply to procedures.

See also: `agn_getutype`.

### **agn\_setutypestring**

```
void agn_setutypestring (lua_State *L, int idxobj, const char *str);
```

Sets the string `str` as the user-defined type of the procedure, sequence, set, or pair at stack position `idxobj`.

### **agn\_size**

```
int agn_size (lua_State *L, int idx);
```

Returns the number of items currently stored to the array and the hash part of the table at stack index `idx`.

### **agn\_ssize**

```
int agn_ssize (lua_State *L, int idx);
```

Returns the number of items currently stored to the set at stack index `idx`.

### **agn\_sstate**

```
void agn_sstate (lua_State *L, int idx, size_t a[])
```

Returns the actual number of items and the current maximum number of items allocable to the set at index `idx` in `a`, a C array with two entries. The actual number of items is stored to `a[0]`, the current allocable size to `a[1]`.

### **agn\_tablestate**

```
void agn_tablestate (lua_State *L, int idx, size_t a[])
```

Returns the number of key~value pairs allocable and actually assigned to the respective array and hash sections of the table at index `idx` by storing the result in `a`, a C array with four entries.

The number of key~value pairs currently stored in the array part is stored to `a[0]`, the number of pairs currently stored in the hash part to `a[1]`. The number of allocable key~value pairs to the array part is stored to `a[2]`, and the number of allocable key~value pairs to the hash part is stored to `a[3]`.

## agn\_tocomplex

```
agn_Complex agn_tocomplex (lua_State *L, int idx)
```

Assumes that the value at stack index `idx` is a complex value and returns it as a `lua_Number`. It does not check whether the value is a complex number.

## agn\_tonumber

```
lua_Number agn_tonumber (lua_State *L, int idx)
```

Assumes that the value at stack index `idx` is a number and returns it as a `lua_Number`. It does not check whether the value is a number. The strings or names 'undefined' and 'infinity' are recognised properly.

## agn\_tonumberx

```
lua_Number agn_tonumberx (lua_State *L, int idx, int *exception)
```

If the value at stack index `idx` is a number or a string containing a number, it returns it as a `lua_Number`. The strings or names 'undefined' and 'infinity' are recognised properly. If successful, exception is assigned to 0.

If the value could not be converted to a number, 0 is returned, and exception is assigned to 1.

## lua\_pushfail

```
void lua_pushfail (lua_State *L);
```

This macro pushes the boolean value **fail** onto the stack.

## lua\_pushfalse

```
void lua_pushfalse (lua_State *L);
```

This macro pushes the boolean value **false** onto the stack.

## lua\_pushundefined

```
void lua_pushundefined (lua_State *L);
```

Pushes the value **undefined** onto the stack.

### lua\_pushtrue

```
void lua_pushtrue (lua_State *L);
```

This macro pushes the boolean value **true** onto the stack.

### lua\_rawset2

```
void lua_rawset2 (lua_State *L, int idx);
```

Similar to `lua_settable`, but does a raw assignment (i.e., without metamethods).

Contrary to `lua_rawset`, only the value is deleted from the stack, the key is kept, thus you save one call to `lua_pop`. This makes it useful with `lua_next` which needs a key in order to iterate successfully.

### lua\_rawsetilstring

```
void lua_rawsetilstring (lua_State *L, int idx, int n, const char *str,  
                        int len);
```

Does the equivalent of `t[n] = string`, where `t` is the table at the given valid index `idx`, `n` is an integer, `string` the string to be inserted and `len` the length of then string. This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

### lua\_rawsetikey

```
void lua_rawsetikey (lua_State *L, int idx, int n);
```

Does the equivalent of `t[n] = k`, where `t` is the value at the given valid index `idx` and `k` is the value just below the top of the stack.

This function pops the topmost value from the stack and leaves everything else untouched. The assignment is raw; that is, it does not invoke metamethods.

### lua\_rawsetinumber

```
void lua_rawsetinumber (lua_State *L, int idx, int n, lua_Number num);
```

Does the equivalent of `t[n] = num`, where `t` is the value at the given valid index `idx`, `n` is an integer, and `num` an Agena number (a C double).

This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

## lua\_rawsetistring

```
void lua_rawsetistring (lua_State *L, int idx, int n, const char *str);
```

Does the equivalent of  $t[n] = \text{str}$ , where  $t$  is the value at the given valid index  $\text{idx}$ ,  $n$  is an integer, and  $\text{str}$  a string.

This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

## lua\_rawsetstringlint

```
void lua_rawsetstringlint (lua_State *L, int idx, const char *str,
    int len, int n);
```

Does the equivalent of  $t[\text{str}] = n$ , where  $t$  is the value at the given valid index  $\text{idx}$ ,  $\text{str}$  a string,  $\text{len}$  the length of  $\text{str}$ , and  $n$  an integer.

This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

## lua\_rawsetstringnumber

```
void lua_rawsetstringnumber
    (lua_State *L, int idx, const char *str, lua_Number n);
```

Does the equivalent of  $t[\text{str}] = n$ , where  $t$  is the value at the given valid index  $\text{idx}$ ,  $\text{str}$  a string, and  $n$  a Lua number.

This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

## lua\_sdelete

```
void lua_sdelete (lua_State *L, int idx);
```

Deletes the element residing at the top of the stack from the table at stack position  $\text{idx}$ . The element at the stack top is popped thereafter.

## lua\_seqgeti

```
void lua_seqgeti (lua_State *L, int idx, int n);
```

Gets the  $n$ -th item from the sequence at stack index  $\text{idx}$  and pushes it onto the stack.

### lua\_seqgetinumber

```
lua_Number lua_seqgetinumber (lua_State *L, int idx, int n);
```

Returns the value `t[n]` as a *lua\_Number*, where `t` is a sequence at the given valid index `idx`. If `t[n]` is not a number, the return is `HUGE_VAL`. The access is raw; that is, it does not invoke metamethods.

### lua\_seqinsert

```
void lua_seqinsert (lua_State *L, int idx);
```

Inserts the element on top of the Lua stack into the sequence at stack index `idx`. The element is inserted at the end of the sequence. The value added is popped from the stack.

### lua\_seqnext

```
int lua_seqnext (lua_State *L, int index);
```

Pops a key from the stack, and pushes the next key~value pair from the sequence at the given index. If there are no more elements in the sequence, then **lua\_seqnext** returns 0 (and pushes nothing). To access the very first item in a sequence, put **null** on the stack before (with **lua\_pushnil**).

While traversing a sequence, do not call **lua\_tolstring** directly on the key. Recall that **lua\_tolstring** changes the value at the given index; this confuses the next call to **lua\_seqnext**.

### lua\_seqrawget

```
void lua_seqrawget (lua_State *L, int index);
```

Pushes onto the stack the sequence value `t[k]`, where `t` is the sequence at the given valid index `index` and `k` is the value at the top of the stack.

This function pops the key from the stack (putting the resulting value in its place). The function does not invoke any metamethods.

## lua\_seqrawset

```
void lua_seqrawset (lua_State *L, int index);
```

Does the equivalent to  $s[k] := v$ , where  $s$  is a sequence at the given valid index `index`,  $v$  is the value at the top of the stack, and  $k$  is the value just below the top.

This function pops both the key and the value from the stack. It does not invoke any metamethods.

## lua\_seqrawsetilstring

```
void lua_seqrawsetilstring (lua_State *L, int idx, int n, const char *str,
                             int len);
```

Does the equivalent of  $s[n] = \text{string}$ , where  $s$  is the sequence at the given valid index `idx`,  $n$  is an integer, `string` the string to be inserted and `len` the length of then string.

This function leaves the stack unchanged. The assignment is raw; that is, it does not invoke metamethods.

## lua\_seqseti

```
void lua_seqseti (lua_State *L, int idx, int n);
```

Sets the value at the top of the stack to index  $n$  of the sequence at stack index `idx`. If the value added is **null**, the entry at sequence index  $n$  is deleted and all elements to the right of the value deleted are shifted to the left, so that their index positions get changed, as well.

The function pops the value at the top of the stack.

If there is already an item at position  $n$  in the sequence, it is overwritten.

If you want to extend a current sequence, the function allows to add a new item only at the next free index position. Larger index positions are ignored, but the value to be added is popped from the stack, as well.

## lua\_seqsetinumber

```
void lua_seqsetinumber (lua_State *L, int idx, int n, lua_Number num);
```

Sets the given Agena number `num` to index  $n$  of the sequence at stack index `idx`.

### **lua\_seqsetistring**

```
void lua_seqsetistring (lua_State *L, int idx, int n, const char *str);
```

Sets the given string `str` to index `n` of the sequence at stack index `idx`.

### **lua\_sinsert**

```
void lua_sinsert (lua_State *L, int idx);
```

Inserts an item into a set. The set is at the given index `idx`, and the item is at the top of the stack.

This function pops the item from the stack.

### **lua\_sinsertlstring**

```
void lua_sinsertlstring (lua_State *L, int idx, const char *str, size_t l);
```

Sets the first `l` characters of the string denoted by `str` into the set at the given index `idx`.

### **lua\_sinsertnumber**

```
void lua_sinsertnumber (lua_State *L, int idx, lua_Number n);
```

Sets the number denoted by `n` into the set at the given index `idx`.

### **lua\_sinsertstring**

```
void lua_sinsertstring (lua_State *L, int idx, const char *str);
```

Sets the string denoted by `str` into the set at the given index `idx`.

### **lua\_srawget**

```
void lua_srawget (lua_State *L, int index);
```

Checks whether the set at index `idx` contains the item at the top of the stack. The function pops the key from the stack putting the Boolean value `true` or `false` in its place.

The function does not invoke any metamethods.

## lua\_srawset

```
void lua_srawset (lua_State *L, int index);
```

Does the equivalent to `insert v into s`, where `s` is the set at the given valid index `index`, `v` is the value at the top of the stack.

This function pops the value from the stack. It does not invoke any metamethods.

## lua\_usnext

```
int lua_usnext (lua_State *L, int index);
```

Pops a key from the stack, and pushes the next item twice (!) from the set at the given `index`. If there are no more elements in the set, then `lua_usnext` returns 0 (and pushes nothing). To access the very first item in a set, put `null` on the stack before (with `lua_pushnil`).

While traversing a set, do not call `lua_tolstring` directly on an item, unless you know that the item is actually a string. Recall that `lua_tolstring` changes the value at the given index; this confuses the next call to `lua_usnext`.

## luaL\_getudata

```
void *luaL_checkudata (lua_State *L, int narg, const char *tname,
                      int *result);
```

Checks whether the function argument `narg` is a userdata of the type `tname`. Contrary to `luaL_checkudata`, it does not issue an error if the argument is not a userdata, and also stores 1 to `result` if the check was successful, and 0 otherwise.

### A1 Operators

Unary operators are:

`abs`, `arctan`, `assigned`, `bea`, `char`, `copy`, `cos`, `cosh`, `entier`, `even`, `exp`, `filled`, `finite`, `float`, `gammaln`, `imag`, `int`, `isnull`, `join`, `left`, `ln`, `lower`, `nargs`, `not`, `qsadd`, `real`, `replace`, `right`, `sadd`, `sign`, `sin`, `sinh`, `size`, `sqrt`, `tan`, `tanh`, `trim`, `type`, `unique`, `upper`, `typeof`, `-` (unary minus).

Binary operators are:

`in`, `intersect`, `minus`, `shift`, `split`, `subset`, `union`, `xsubset`, `+` (addition), `-` (subtraction), `*` (multiplication), `/` (division), `\` (integer division), `%` (modulus), `^` (exponentiation), `**` (integer exponentiation), `..` (concatenation), `=` (equality), `<` (less than), `<=` (less or equal), `>` (greater than), `>=` (greater or equal), `$` (substring), `:` (pair constructor), `!` (complex constructor).

### A2 Metamethods

The following metamethods were inherited from Lua 5.1:

Index to metatable	Meaning
'__index'	Procedure invoked when a value shall to be read from a table, set, sequence, or pair.
'__gc'	Garbage collection (for userdata only).
'__mode'	Sets weakness of a table.
'__add'	Addition of two values.
'__sub'	Subtraction of two values.
'__mul'	Multiplication of two values.
'__div'	Division of two values.
'__mod'	Modulus.
'__pow'	Exponentiation.
'__unm'	Unary minus.
'__eq'	Equality operation.
'__lt'	Less-than operation.
'__le'	Less-than or equals operation.
'__concat'	Concatenation.
'__call'	See Lua 5.1 manual.
'__tostring'	Method for pretty printing values at stdout.

Table 15: Metamethods taken from Lua

The `'__len'` metamethod in Lua 5.1 to determine the size of an object was replaced with the `'__size'` metamethod.

The following methods are new in Agena:

Index to metatable	Meaning
'abs'	<b>abs</b> operator
'arctan'	<b>arctan</b> operator
'cos'	<b>cos</b> operator
'eeq'	strict equality operator (==)
'entier'	<b>entier</b> operator
'even'	<b>even</b> operator
'exp'	<b>exp</b> operator
'finite'	<b>finite</b> operator
'gammaln'	<b>gammaln</b> operator
'in'	in binary operator (for tables and sequences only)
'int'	<b>int</b> operator
'intdiv'	integer division
'ipow'	exponentiation with an integer power
'ln'	<b>ln</b> operator
'__qsadd'	<b>qsadd</b> operator for table or sequence based user-defined types
'__sadd'	<b>sadd</b> operator for table or sequence based user-defined types
'sign'	<b>sign</b> operator
'size'	<b>size</b> operator
'sin'	<b>sin</b> operator
'sqrt'	<b>sqrt</b> operator
'tan'	<b>tan</b> operator
'__writeindex'	Procedure invoked when a value shall to be written to a table, set, sequence, or pair.

Table 16: Metamethods introduced with Agena

### A3 System Variables

Agena lets you configure the following settings:

System variable	Meaning
EnvAgenaPath	path to the main Agena directory
_EnvLongTable	If set true, then each key~value pair in a table will be printed at a separate line, otherwise a table will be printed like sets or sequences.
_EnvMaxLong	The maximum integral value of the C type long on your platform; do not change this value.
_EnvMinLong	The minimum integral value of the C type long on your platform; do not change this value.
_EnvMore	number of entries in tables and sets printed by <b>print</b> and the end-colon functionality before issuing the `press any key` prompt.

System variable	Meaning
_EnvPrintNewLineAfterInput	If set to true, a newline is printed at the console after entering a statement. Default: unassigned, i.e. no newline.
_EnvPrintNoNewLine	If it is set <b>true</b> , the <b>print</b> function does not print a newline when it quits, otherwise a newline is printed.
_EnvPrintZeroedCmplxVals	When set to true, real and imaginary parts of complex values close to zero are rounded to zero on output. (Note that internally, complex values are not rounded.)
_EnvRelease	A sequence containing the string `AGENA`, the main interpreter version as a number, the subversion as a number, and the patch level as a number, as well.
_EnvWithProtected	set of names (passed as strings) that cannot be overwritten by the with function.
_EnvWithVerbose	If set to false, the <b>with</b> function will not display warnings, the init string, and the short names assigned.
PROMPT	Defines the prompt Agena displays at the console
_RELEASE	Release information on the installed Agena release, returned as a string, e.g. 'AGENA >> 0.90.0'.

Table 17: System variables

## A4 Command Line Usage

Agena can be used in the command line as follows:

```
agena [options] [script [arguments]]
```

This means that any option, an Agena script, and the arguments are all optional. If you just enter

```
shell> agena
```

Agena is started in interactive mode immediately.

There are two ways to run an Agena script with some arguments and then return to the command line immediately without entering interactive mode:

### A4.1 Using the **-e** Option

We may write a script with a text editor, e.g. one to print the sine of a number. This script may look like the following two lines:

```
n := n or Pi; # if n is not set from the shell, just assign Pi to n
writeline(sin(n));
```

This script prints the sine to a user-given numeric argument which is passed by using the `-e` option and a string containing a valid Agena statement. It uses a variable `n` which you must assign via the `-e` option:

```
shell> agenat -e "n := Pi/2" sin.agn
1
```

Note that you first have to enter the `-e` option along with the Agena statement, and then the name of the script.

## A4.2 Using the internal `args` Table

Everything you pass to the interpreter from the command line is stored in the **args** table.

The name of the script is always stored at index 0, the arguments are stored at the positive indices 1, 2, etc., in the order given by the user. Any options are accessible via negative keys. The name of the interpreter is always at the smallest index.

Consider the following script called 'args.agn':

```
for i, j in args do
    writeline(i, j, delim~'\t')
od;
```

If it is run, the output is:

```
shell> agenat args.agn 0
-1      agenat
0       args.agn
1       0
```

Just play around with this a little bit.

Let us use our new knowledge: The script 'ln.agn' requires a string and a number and calculates the natural logarithm of this number. The number entered at the command line is entered into the **args** table as a string, so you first must convert it into a `real` number.

```
arg1 := args[1];
arg2 := toNumber(args[2]);

try arg1 as string;
try arg2 as number;

writeline(arg1, ln(arg2));
```

Use it:

```
shell> agena ln.agn "The natural logarithm of 1 is: " 1
The natural logarithm of 1 is: 0
```

### A4.3 Running a Script and then entering interactive Mode

The `-i` option allows you to enter the interactive level after running a script or passing other options to Agena. The position of the `-i` option does not matter. The following shell statement resets the Agena prompt and starts the interpreter:

```
shell> agena -i -e "_PROMPT := 'AGENA> '"
AGENA>
```

### A4.4 Running Scripts in UNIX

If you use Agena in UNIX, then you can execute Agena scripts directly by just entering the name of the script followed by any arguments (if needed).

Just insert the following line at the head (i.e. line 1) of each script:

```
#!/usr/local/bin/agena
```

and set the appropriate rights for the script file (e.g. `chmod a+x scriptname`).

An example:

```
bash> ./sin.agn 1
0.8414709848079
```

In all other operating systems, the first line is ignored by the interpreter, so you do not have to delete the first line of the script in order to use scripts you have originally written under UNIX.

### A4.5 Command Line Switches

The available switches are:

Option	Function
<code>-b</code>	print compilation time of Agena binary with startup message
<code>-e "stat"</code>	execute string "stat" (double quotes needed)
<code>-h</code>	help information
<code>-i</code>	enter interactive mode after executing `script` or other options
<code>-l</code>	print licence information
<code>-n</code>	do not run initialisation file `agena.ini`
<code>-p path</code>	sets path to main Agena folder <path>, overriding the standard initialisation procedure for <code>_EnvAgenaPath</code> . The path does not need to be put in quotes.
<code>-r name</code>	readlib library <name>. The name of the library does not need to be put in quotes.
<code>-v</code>	show version information

Option	Function
--	stop handling options
-	execute stdin and stop handling options

## A5 Define your own Printing Rules for Structures

You can tell Agena how to output tables, sets, sequences, pairs, and complex values at the console.

With each call to the internal printing routine, the interpreter uses the respective `_EnvPrint` function defined in the `lib/library.agn` file. You may change these functions according to your needs.

Table index	Functionality
<code>_EnvPrint.Table</code>	defines how to print a table, overriding the built-in default
<code>_EnvPrint.Set</code>	defines how to print a set, overriding the built-in default
<code>_EnvPrint.Sequence</code>	defines how to print a sequence, overriding the built-in default
<code>_EnvPrint.Pair</code>	defines how to print a pair, overriding the built-in default
<code>_EnvPrint.Complex</code>	defines how to print a complex value, overriding the built-in default

Alternative `_EnvPrint` functions might look like the following:

```
> _EnvPrint.Set := proc(s) is
>   write('set(');
>   if size s > 0 then
>     for i in s do
>       write(i, ', ');
>     od;
>     write('\b\b');
>   fi;
>   write(')');
> end;

> _EnvPrint.Complex := proc(s) is
>   write('cmplx(', real(s), ', ', imag(s), ')');
> end;

> {1, 2}:
set(1, 2)

> 1*2*I:
cmplx(1, 2)
```
